celluloid can be shaped to the size of the opening with scissors, allowing sufficient edge to overlap the opening in the skull so that it will rest upon the outer table of the bone. The plates I have employed are made from the convex top of an ordinary celluloid powder puff box, the convexity of which very nearly conforms to the arc of the skull. As boiling destroys the convexity, those that I have used I have sterilized by washing with soap and water, and leaving overnight in a solution of bichloride 1 to 500, and transferring to a normal salt solution before the operation is begun. After shaping the plate as nearly as possible to the opening in the skull, three or four points are drilled obliquely through the bone, beginning about one fourth of an inch beyond the edge and coming out just about the margin of the inner table.

It is well to place a spatula or some protecting plate between the dura and skull to prevent a sudden passage of the drill through the inner table into the brain.

Into these openings silver wires No. 22 are passed and left in position. Corresponding openings are now drilled in the plate, and the inner ends of the wires are brought outward through these. Twisting the wires now draws the plate down snugly into position, and the twisted ends are cut off, and bent so that they can be pushed under the edge of the plate.

In the temporal region I have relied upon pushing the lower end of the plate under the muscle, as it is very difficult to drill the lower angle of the bone opening.

The scalp is now closed over by the ordinary method of the operator, though personally I always close these wounds with a continuous suture of plain catgut, because this renders it unnecessary to ligate any of the scalp vessels, as the even pressure of the continuous stitch controls hæmorrhage perfectly. It is well to bring a drain of gauze or a few strands of catgut from the space between the scalp and plate, as I have had to contend in two instances with quite a large serous collection at this point that required several weeks for absorption.

It is also well to place the dressings somewhat snugly over the wound, so that pressure will prevent oozing and keep the scalp well down upon the plate.

Healing is usually complete in one week, and the patients are out of bed in half this time. I have seen absolutely no irritation result from the plate in any instance, and I am certain that these patients are far more comfortable than those in whom the brain is left unprotected under the

scalp. The cases in which I have so far applied these plates are six, whose histories are given below:

REPORT OF CASES.

CASE I.—*Cyst of the Brain Producing Epilepsy.* Mr. W., aged 50 years, received a compound fracture of the left orbital arch and frontal bone in a railroad accident twenty-three years before. Within less than a year he was seized with an epileptic convulsion, and these had been increasing in frequency and severity since that time, so that now he had had three or four within the previous few months. His mental activity had been

cut out for a space covering an ellipse, one and one half inch by two inches, extending from the supraorbital ridge upward and outward. The cyst was found to be about the size of an English walnut, extending from the original seat of the fracture upward and outward towards the speech centre. It was evacuated, and drained, after scratching its internal wall at various points with a needle. On account of the extensive removal of bone the frontal sinus was opened, thus making a direct connection between the cavity of the nose and the brain, and during the operation air was forced up through the sinus. After stitching the dura in position, the outer end of the frontal sinus was packed with iodoform gauze, and a notch was made in the inner edge of the plate, which was anchored in position by the methods described. Patient had a convulsion the night following the operation, but the course was otherwise uneventful. The gauze in frontal sinus was left six days, and, after removal, the sinus gradually closed without trouble. Now eleven months after operation it is impossible across the room to detect any evidence of the operation, the scalp lying evenly and smoothly over the plate, which is not discoverable even by close examination. The general condition of the patient has been excellent, but there have been one or two convulsions since the operation. His speech has much improved.

CASE II.—*Jacksonian Epilepsy.* M. F., aged 25 years, male. This patient had been operated upon three times for traumatic epilepsy, twice by Dr. McGannon, of Nashville, Tenn., and once by myself. He still has epilepsy, and his condition is supposed to be incurable, and he suffers on account of the large exposure of his brain, where the bone has been removed. Hearing of the plate that I had inserted in the above mentioned case, he consulted me with the view of having the opening in his skull covered. The examination showed three openings in the skull, somewhat irregularly joined, and extending over a large part of the Rolandic area. The brain pulsed freely, and he complained that he suffered at all times from the direct exposure of the brain to pressure and to blows, even turning upon his pillow at night when he lay upon this side, seeming to precipitate convulsion. Operation May 15, 1904, at St. Joseph's Infirmary. Under ether a large curved incision twelve inches long was made so as to encircle the whole area, extending from the external angular to the posterior process. The separation of the flap was difficult at some points on account of adhesions between the scalp and dura, but these were carefully separated over the whole pulsating surface. With rongeur the edges of the bone openings were cut away so as to make the opening more even and symmetrical. The bone, especially thick, was cut away downward, showing the brain here to have been apparently compressed and its convolutions atrophied. The opening, when complete, was an ellipse three by four inches. The plate employed was a circle three and a half inches in diameter, being the bottom of a large puff box, which unfortunately was less convex than the top, but it

CASE I.—This patient has a plate 1½ x 2 inches in left side of forehead. Now in place more than one year.

much impaired, and from formerly having been a fluent talker he now spoke with slowness and difficulty, finding much trouble at times in selecting his words. Diagnosis was made of cyst of the brain, involving the frontal lobe of the left side, and extending backwards towards the speech centre, to the removal of which he consented. As the opening in the skull for the removal of the cyst and the necessary exploration would be necessarily large, and knowing that it would result in such an unsightly depression in the patient's forehead, I gained his consent to carry out what I had long contemplated doing, the experiment of the application of a plate of celluloid. The skull at operation was demonstrated to be very thick at the point of injury, and the thickened bone was

was selected on account of its larger size. This was perhaps a mistake, for the want of convexity permitted the atmospheric pressure to dent in the plate somewhat. Recovery in this case was uneventful, the patient sitting up in the yard on the third day after operation. Quite a quantity of fluid collected between the scalp and the plate, and on account of the too early absorption of the catgut drain. This subsequently disappeared without causing any trouble. The patient immediately felt better, and his tendency to convulsions grew much less. It was possible to tap upon this plate with the fingers without causing any disagreeable jar of his brain, and he was enabled to lie upon this side upon his pillow without any disagreeable sensation. Though this was done simply to protect his brain from external injury, and not with the view of curing his epilepsy, he has been much benefited, and the contrast between the comfort before and after the protecting plate is very great.

CASE III.—*Jacksonian Epilepsy from Brain Cyst.* J. A. M., aged 45 years, suffering from epilepsy resulting from a blow upon the side of the head received twelve years before. Convulsions began four months after injury, and had increased in frequency and severity until now he was completely disabled from work. Diagnosis, brain cyst with resulting epilepsy. Operation July, 1904, St. Joseph's Infirmary. Skull was opened over the slight depression where the injury originally was received, and a circle of bone one and a half inches in diameter removed. When the dura was opened, a cyst was encountered practically as large as a hen's egg. This was evacuated, and treated as in Case I, and the plate inserted by the same method. His progress was uneventful until the end of the first week, when he began to have increasing stupor, while at the same time there was a large collection of fluid under the scalp and over the plate. As his temperature was at the same time very high, it was feared that infection had taken place, but removal of the fluid showed it to be clear serum. Seeking further into the cause of this condition, it was found that his urinary excretion was very small, and this proved to be the cause of his stupor and high temperature. He passed into a complete coma, and there was a total suppression of urine for twenty-seven hours. Fortunately the excretion of urine began under use of saline enema and digitalis hypodermically, and he gradually progressed to recovery, leaving for his home one month after operation. There was a large collection of fluid between the plate and the scalp, which required about one month for absorption. Subsequent history shows gradual improvement, and no trouble from the plate.

CASE IV.—*Exploratory Operation Upon the Brain.* Mr. C., aged 60 years, had been suffering for some months with vague symptoms of brain pressure, which could not be localized by any focal symptoms, except that optic neuritis and bulging of the left eye ball pointed to some pressure not far behind the orbit. There was also a motor oculi paresis. Examination of the urine

showed patient was also suffering from chronic Bright's disease. On account of his desperate condition, an exploratory operation was decided upon, with the view of reaching any growth that there might be in the anterior portion of the brain. A large opening about two inches in diameter was made just above the zygoma and behind the external angular process for the frontal bone, with the view of gaining access to the anterior fossa of the skull. After opening the dura I was surprised to find to what extent the base of the skull and under surface of the brain could be explored with the finger. As my finger was removed the first time there was a large gush of cerebrospinal fluid, or some other fluid collection, which gave me freer access subsequently on account of reducing the intracranial pressure. The finger was passed inward in the anterior fossa of the skull until the anterior clinoid process and the falx cerebri could be felt distinctly. Passing it along the lesser wing of the sphenoid permitted exploration of the fissure of Sylvius. Passing the finger downward and backward the middle fossa of the base of the skull and the temporo-sphenoidal lobe could be felt over all of its surface. Next the entire surface of the cerebrum could be swept over with the finger up as far as the falx cerebri, and back over the convexity of the cerebrum as far as the mastoid process. Nothing tangible was discovered except perhaps an increase of cerebrospinal fluid or a cystic collection. As sometimes happens, in spite of the fact of no definite lesion being found, his brain condition was much improved, his intellect was clearer, and the eye paralysis improved. A plate was inserted as in the former cases and the healing was perfect without any change of the original dressing. Unfortunately, on the twelfth day after operation, this patient was seized with uræmic convulsions, and with intervals of only a few minutes' rest these continued until his death two days later. An autopsy was refused, so that the exact condition remains a mystery.

CASE V.—*Cerebral Sinus Following Operation for Cyst.* J. A. P., aged 30 years, was operated upon three months before by Dr. Floyd W. McRae, for Jacksonian epilepsy, resulting from a compound fracture just behind the angular process of the frontal, with resulting brain cyst. By some means his wound was badly infected, and some months afterwards continued to discharge from the sinus extending down to the brain. For this condition he was sent to me by Dr. McRae with the request that I operate upon him, and insert a plate. Operation July 7, 1904, St. Joseph's Infirmary. An incision was made encircling the former one, exposing quite an area of bone around the seat of the former opening. The bone was cut away to a circle about one and three quarter inch in diameter, adhesions between the scalp and dura, especially at the point of entrance of the sinus, being dissected away as well as possible. The dura was not opened except at the point of the sinus. The plate was inserted in the usual manner, but in spite of all precautions there was a certain amount of infection along the suture openings, though there was apparently no

deep infection in the wound. As before, there persisted a sinus which discharged cerebrospinal fluid, which was treated first by Dr. McRae and then myself for several months. Attempts were made to close the tract by application of pure carbolic acid, passing it from the lower angle across the plate to the upper edge. This was successful and finally the sinus closed, but a few days afterwards the patient called at my office complaining of headache. Two days later I saw him at home, suffering with intense headache and very stupid. His relief through the treatment was only temporary, his stupor increased steadily, and three or four days later, when seen by my assistant during my illness, he was found profoundly comatose, with a pulse of 45 to the minute. He was moved at once to the infirmary, and a diagnosis was made of brain abscess. In pressing against the plate it was found to be somewhat pushed outward by the intracranial pressure.

Operation, Sunday morning, October ——— St. Joseph's Infirmary. Under either the scalp incision was opened about along the former line, and the plate quickly uncovered. There was no evidence whatever of any irritation or infection around the plate, but one of the wires which anchored it had been broken. Removing the plate showed the dura, which was rough at the time of the operation, to be perfectly smooth and uniform in its surface, but just in the centre of the area uncovered was a slightly discolored pulsating spot. Here a small opening was made with the point of a scalpel, and a pair of artery forceps was plunged into the brain through this opening, and when the blades were separated there was a tremendous gush of pus from an abscess in the brain. Introduction of the finger showed this cavity to be about the size of a hen's egg. A drainage tube was introduced into this cavity and brought out through a puncture through the centre of the flap, and the flap sutured in place. This tube was shortened from day to day, and finally the abscess closed entirely in about six weeks. The interesting feature about this case is that the patient now has a large pulsating area, that was originally covered over by the plate, and it is so uncomfortable, as compared with his former condition, that even though he has already undergone three operations, he asks that a plate be reinserted for the purpose of comfort and protection.

CASE VI.—*Insanity Following Depressed Fracture and Brain Cyst.* B. S., white, male, aged 36 years. When 18 years of age, in an altercation he received a blow over the right temple resulting in a depressed fracture. Within a few months his mind became disturbed, and it was necessary to commit him to the Alabama Insane Asylum. The form of his mania was of the nature of a harmless dementia. He continued in this condition until five years later, when he was operated upon by Dr. A. S. Talley, of Birmingham, Ala. Following the operation there was such decided improvement that he was taken home. His mother says that as soon as the opening began to "sink in and get hard," his mind again grew worse, and he was recommitted to the asylum. Another operation was discouraged by the officer

of the asylum, but he came to me in December last for operation. Examination revealed a deep crater-like depression behind the external angular process upon the right side, the skin tightly adherent. The centre of the depression was hard and firm. Operation, December 28, 1904. St. Joseph's Infirmary. Gave ether anaesthesia. A horseshoe incision surrounded the area of former operation, and the skin was with difficulty separated from the underlying dura. The thickened dura was opened, and found one eighth of an inch thick, covering a well defined cyst. A part of the anterior wall was cut away, and the cavity of the cyst needled. A plate of celluloid was anchored by the usual method, and the wound closed with continuous catgut suture. Complete healing in one week, plate smoothly covering the opening, and undetectable by examination. His improvement mentally began at once, and a letter from his mother a few days since informs me that his condition is so much improved that she is preparing to take him home in about four weeks.

Though the duration of these cases does not give a very long observation of results, I feel safe in making the following claims for the routine application of this principle to all operations, where we are compelled to make openings of any size in the skull, or where a larger area has been removed by accident:

First.—It is safe, does not add any extra risk to the operation, and the materials required are easily obtainable.

Second.—It not only removes the pressure and irritation which we are endeavoring to combat, but by its resistance prevents a recurrence, from the subsequent consolidation of the coverings in a false position, due to atmospheric pressure.

Third.—It protects the patient from external influences, and not only makes him feel safer, but actually safer.

Fourth.—It enables us to be much more untrammelled in the amount of bone that we can remove.

Fifth.—It prevents deformity, which, especially when beyond the hair line, is necessarily great in large bone removals, and this produces an important cosmetic result.

Sixth.—It does away with the necessity for introducing substances for preventing adhesion between the scalp and dura mater.

Seventh.—In the event of a necessity for subsequent invasion of the brain it enables us rapidly to reach the seat of trouble, without finding adhesions to confuse and obstruct.

The Fat of the Land.—Dr. John W. Streeter's book of this name, having passed through many editions, has been issued in paper covers by the Macmillan Company at 25 cents. Every country practitioner who has an acre or more of land should read this charming and instructive work.

RECURRING SUBLUXATION OF THE FEMUR AS AN UNUSUAL SEQUEL TO AN INCOMPLETE FRACTURE OF THE NECK OF THE FEMUR.

By PRESCOTT LE BRETON, M. D.,

BUFFALO,

ASSISTANT ATTENDING ORTHOPÆDIC SURGEON TO THE ERIE COUNTY HOSPITAL.

Owing to the recent work of Dr. Whitman, of New York, an increased interest has been taken of late in the subject of fractures of the neck of the femur, especially of the incomplete or greenstick fractures in children. The ordinary disability resulting in untreated cases of this kind is usually diagnosticated as some form of hip disease by the family physician, but it is really a traumatic coxa vara with its own special symptoms and treatment. The writer wishes to report the following case which resulted in a unique condition:

E. B., a schoolgirl, aged 15 years. Referred by Dr. Scofield, of Bemus Point, N. Y., and Dr. M. N. Bemus, of Jamestown, N. Y., on November 17, 1903. A large, strong girl, weighing one hundred and twelve pounds. The family history and the previous personal history were negative. Fourteen months before coming to Buffalo, this girl had fallen on the street, striking her left hip. Although in considerable pain, she was able to get up and walk home. She remained home for three weeks, limping about the house. While walking she flexed her thigh and leg and stepped on the ball of the foot, rotating the leg outward slightly. This position in walking continued from the date of her first injury to the time the writer saw her. After the three weeks mentioned she began to go to school again, complaining always of a slight pain relieved best by the attitude above described (see cut).

Five months later she received a push from another girl which strained the same hip and caused increased soreness. Three months after this second injury, when about to sit down on a chair, another child pulled the chair away and she fell to the floor, striking the same hip. These secondary injuries seemed to be of minor importance.

During the previous three months the girl had noticed on attempting to extend her thigh while in the upright position, a sudden jerk or slip at the hip, which caused a sharp pain. Walking became progressively more of an effort, and she tired readily.

Examination.—A well developed, strong girl, large for her age. While standing or walking she kept the thigh and leg somewhat flexed and did not bring the heel to the ground. Slight outward rotation was evident. There was a marked limp and the left hip was prominent. On lying down the limb was easily straightened into a normal position, but on arising the deformed position was immediately resumed. On attempting to

forcibly straighten the thigh in the upright position, the trochanter jumped suddenly forward and became less prominent. It seemed as if the head of the bone slipped violently into its socket, riding over a bony ridge, which must have been the rim of the acetabulum or an artificial ridge formed by the abnormal conditions. A corresponding ful-

FIG. 1. Showing attitude that relieved pain.

ness could be felt under the gluteal muscles, which disappeared as the slipping occurred. The sensation was very similar to that felt in a case of congenital dislocation when the dislocation is reduced.

There was no atrophy of thigh or calf. Spasm of a voluntary nature resisted every movement of the thigh, but there was no limitation of motion. The left leg was three eighths of an inch longer than the right (probably due to overgrowth). The slipping of the bone, so marked in the upright position, was absent while she was prone. Sensation and reflexes were normal.

An x ray forwarded by Dr. Bemus showed evidence of a previous injury to the neck of the femur. A tracing of the bones made it appear that partial fracture followed by thickening and lessening of the angle of the neck had occurred, but not enough depression to give the symptoms of a coxa vara.

After study of the case it seemed that the only treatment indicated was to overcome the deformity and the tendency to subluxation. It was very evident that the patient had been throwing abnormal strain for over a year on the capsule of the

FIG. 2.—X ray tracings. A, Left femur; B, Right femur.

joint by this habit of walking, and that only during the past three months had she experienced the sudden pain and jumping forward of the bone. As all parts were in normal position while she was lying down, a modified Lorenz treatment was advised, i. e., to apply a strong plaster of paris cast in this position and hold the leg fixed for some time until the bad habit of walking and tendency to subluxation were cured. This advice was approved by Dr. Roswell Park, who saw the case the next day in consultation.

Accordingly a cast was applied, and it was found necessary to run it from the lower ribs to the left ankle to prevent the girl from assuming her old position. As soon as this was finished, she walked evenly and well without pain, and brought the sole of the foot to the ground for the first time in over a year. After remaining in Buffalo a few days under observation she went home, and returned three months later. The plaster was removed and the girl walked normally, except for a limp, which later disappeared. There was no tendency to subluxation, and the previous slipping movement could not be reproduced. All motions at the hip were free and normal. The knee was quite stiff from its confinement for a short time. An ingrowing toe nail induced by her habit of walking required treatment. The patient wrote some months later that the cure had been complete.

The interesting points in this case were that an unrecognized incomplete fracture had been received which nature repaired. The girl adopted a position to favor the leg, which finally resulted in a stretching of the capsule of the joint and a tendency to luxation, so that while standing and walking the head of the femur was not in the acetabulum. A short period of immobilization by plaster cured this very marked deformity.

20 CARLTON STREET.

Jewish Hospital, Brooklyn.—Only \$35,000 of the necessary endowment fund of \$250,000 remains to be collected for this institution. A fair, to be held in November, is expected to make good the deficiency.

LOSS OF THE SIGN LANGUAGE IN A DEAF MUTE FROM CEREBRAL TUMOR AND SOFTENING.

By CHARLES W. BURR, M. D.,

PHILADELPHIA,

PROFESSOR OF MENTAL DISEASES, UNIVERSITY OF PENNSYLVANIA.

I have been unable to find any statistics concerning the frequency of cerebral apoplexy and brain tumor in deaf mutes. Since the great cause of mutism is local disease of the ear in early childhood, usually the result of some acute infectious fever, the brain itself remaining entirely normal, there is no reason to suppose that deaf mutes are inherently either more or less liable than the general population to become the victims of brain disease later in life. On the other hand, since many of them lead sheltered lives, it is probable that alcoholism and syphilis are less frequent among them than in the world at large and therefore they largely escape two of the commonest and most potent causes of brain disease. There were 40,562 deaf mutes in the United States in 1890, according to the census, and therefore the total number of them suffering from brain disease would be small, even if the percentage were quite high. Disease of such a nature and so situated as to produce loss of the ability to comprehend and to use the sign language (aphasia) must be very infrequent. In a rather careful search of the literature I have not discovered any reports of cases. In the English edition of Oppenheim's text book (p. 455) a case of Grasset's is referred to in which "a deaf and dumb patient, who was able to make himself understood by the use of his fingers (sign language) lost the ability, after disease of the left hemisphere, for the right hand, although this was not paralyzed." I was unable to find Grasset's original description.

The history of the case I report is as follows:

M. B., a white woman, 56 years old, was admitted to the Philadelphia Hospital, March 22, 1905, with right hemiplegia and speechlessness. From friends I learned that she became deaf in early childhood and had never learned to talk. She had been taught the sign language and to read and write well. On December 17, 1904, she fell unconscious on the street, was picked up paralyzed on the right side and was taken to a hospital, whence she was removed to her home on the same day. Soon after consciousness returned, that is, a few hours after the stroke, she regained the power of using the sign language. She had a second stroke on December 20th, a third at the end of January or the beginning of February, 1905, and a fourth and last on February 14, 1905. She permanently and totally lost the ability to use the sign language only after the fourth attack. After the other attacks the loss was temporary

and more or less recovered from. She regained the power of walking after the first attack, but after each subsequent one the right side was more paralyzed and after the fourth there was no return of power. She was never paralyzed on the left side. After which stroke she lost the power of reading and writing is unknown. Dr. Collins informed me that she had not complained of any illness previous to the first stroke.

Examination.—There was complete flaccid palsy of the right arm and leg and the right side of the face. She was conscious. She moved the left arm and leg about in bed, but not with much strength, looked from side to side, and would swallow food put in her mouth. She paid no attention to commands, whether verbal, written, or given in the sign language. When another mute spelt out commands with her (the patient's) fingers, whether of the left or right hand, she paid no attention. There was not anaesthesia to deep pressure on the left side. Tactile sensibility could not be determined. There seemed to be total anaesthesia on the right side. When a pencil was put in her left hand she grasped it awkwardly, but made no attempt to use it. She looked for a moment at pieces of paper on which were written and printed short commands, but made no attempt to do what was ordered. She glanced for a moment at objects put in front of her, but made no attempt to show by pantomime that she understood what they were. She would follow with the eye a moving object brought into the left field of vision, but on the right side paid no attention till it reached or almost reached the middle line. She made no attempt at any time to express thought by pantomime. Emotionally she was inert, expressing neither pleasure or pain, except that when pricked with a pin on the left side she would withdraw the extremity and her face would show pain. She never made gestures. The biceps tendon jerk was present on both sides and the knee jerk and the Achilles jerk were absent. Stroking either sole caused extension of all the toes. There was incontinence of urine and faeces. On March 29th she was seized suddenly with dyspnoea, became bathed in sweat, and in a few minutes died. While in the hospital her temperature was normal, and until the death agony her respiration averaged 22 and her pulse rate 120.

Briefly her final condition was one of right sided hemiplegia and right homonymous hemianopsia following repeated apoplectic strokes, with the loss of all power of expressing or comprehending thought by verbal speech, the sign language, writing, or pantomime. She was not blind in the left field, because she would follow moving objects there, but she gave no evidence of knowing what she saw and all the evidence points toward her being mind blind. She followed objects with her eye as a baby will follow and look at a light or any shining thing.

At the necropsy the left cerebral hemisphere was found to be a little larger than the right, and its convolutions were flattened on the convex surface, especially in the anterior two thirds. The mesial surface bulged in the region of and just in front of the paracentral lobule. At one point

over an area of about one inch in the posterior part of the superior frontal and superior part of the ascending frontal was a dark red soft spot. Palpation over the entire surface gave a feeling of fluctuation beneath. On section the reddish spot spoken of above was seen to belong to a tumor, which extended to the basal ganglia. The tumor was soft and not encapsulated, and was surrounded except on its cortical aspect by an area of softening which involved almost the entire white matter of the hemisphere. The basal ganglia on the left side were almost destroyed by softening. The softening was due in part to hæmorrhage, in part to thrombosis. Histological examination showed the tumor to be a very vascular glioma. The fissure of Rolando on the left side extended into the fissure of Sylvius. There were no other structural anomalies. The right hemisphere was normal. The area of disease was so great that the case is of no interest in localizing speech, except that it shows that the left hemisphere controls language by signs as it does all other forms of language.

The sign language is closely related to pantomime. The latter may be defined as the natural mode of expressing thought, ideas, and emotions, by muscular action other than that of the vocal apparatus. Gestures on the other hand express emotion only and not thought. Pantomime and gesture are natural and inherent. The sign language is an artificial and elaborate system which must be learned to be understood. In actual life deaf mutes always use natural pantomime to help them in expressing ideas.

Disorders of pantomime—amimia and paramimia—have not received as much careful study as speech aphasia. Bastian is of the opinion that amimia varies in the same ratio as the intelligence of the individual affected. In his opinion it does not occur in subcortical lesions and after a lesion in Broca's convolution the disability may be only slight. If on the other hand the auditory word centre is involved and still more the visual word centre there is more and more mental degradation and a corresponding diminution in the individual's power to use and understand pantomime. Charles K. Mills, who has given much time to the subject, states that in true motor aphasia even when complete the patient sometimes shows marked preservation of pantomime, whereas in word deafness and word blindness pantomime is most disturbed on the sensory or receptive side. In mixed sensorimotor aphasia pantomime may be uncertain.

In none of the patients I have examined have I found complete amimia associated with pure motor aphasia. In some patients the ability to use pantomime was remarkable. On the other hand, I can not recall a case of sensory aphasia in which the visual speech centre was diseased in

which there was not either total amimia or, and this more frequently, paramimia, the pantomime being so confused and contradictory as to be incomprehensible. The same condition is found in sensorimotor aphasia. Further, in pure motor aphasia the patient understands pantomime well, whereas in sensory or mixed aphasia he either does not understand at all or only incompletely and with difficulty. Since the sign language is only a highly developed form of pantomime it is probable that the same laws control both and that disease affecting pantomime in a person having the power of speech would affect the sign language in deaf mutes. The sign language is of course learned by vision, and it is probable that in deaf mutes a lesion of the visual centre always causes its loss. Whether there can occur a purely motor disturbance of the sign language, the retention of the ability to comprehend (a normal visual centre), with a loss of the ability to express thought by signs on account of a lesion making it impossible to recall muscular movements necessary to be made is, I believe, unknown. A pure motor amimia in persons who are not deaf mutes, unassociated with any form of verbal aphasia, has never been described.

1327 SPRUCE STREET.

THE PREVENTION OF INSANITY IN ITS INCUBATION BY THE GENERAL PRACTITIONER.*

By J. T. W. ROWE, M. D.,

NEW YORK,

FIRST ASSISTANT PHYSICIAN, MANHATTAN STATE HOSPITAL,
EAST, WARD'S ISLAND.

Within the limitation of a six column paper I shall attempt to express my views on a subject that alienists and psychopathologists have for many years striven to shed light upon, viz., a means or method for preventing the occurrence of insanity.

I expect to be received with due acclaim by superintendents of overcrowded institutions whose greatest efforts are in the direction of keeping out the incoming patients and getting rid of those on their hands, and by industrious students of asylum financial budgets. Constantly renewed volumes of psychiatry have not aided us in the least. The annual reports of superintendents only deplore the steady increase of insanity with no relief in sight. The ratio of recoveries is no better, and assigned causes for the disease are the merest generalizations. Then the question arises, What means are we taking to keep the overcrowding of our hospitals within bounds or to prevent in the slightest degree the occurrence of insanity?

* Read at the sixty-fifth annual meeting of the American Medico-Psychological Association, San Antonio, Tex., April 18 to 21, 1905.

The State hospital has acquired such an enviable reputation nowadays for its luxurious appointments that its freely yielding doors have invited all sorts and conditions of defectives, coming like those in the nursery rhyme, "some in rags, and some in jags, and some in velvet gowns," who might well be kept outside the walls.

The poor relations, "lightly touched," have been unearthed from back rooms and qualified for the journey to their Mecca. And as well the old fatuous chronic, whose alcoholic periodical qualifies him for the workhouse instead of a State hospital, the increasing number of degenerate types and imbeciles which by an easy stretch of the examining powers receive the *imprimatur* of insanity, impel us not only to scan vigorously the doubtful cases presented for our acceptance, but also to speed the parting guests who complaisantly settle down to the amenities of asylum life and share with relatives the fear only that they may be discharged to the short commons of their family circle.

We perhaps do not appreciate the importance of a frequent rounding up of the population for chronic harmless dements who should be discharged to their friends. Many of these patients could be liberated without danger to themselves or others; at any rate the patient should have the benefit of the doubt or be turned over to his local department of poor.

We are all doubtless familiar with cases where the relatives refuse to be comforted because we object to discharge the patient upon their first request and later, when notified to remove him, promptly discontinue visits to patient and hospital, and invoke political and charitable aid to have him retained in the institution, alleging fear of personal harm, or perhaps, newly formed outside attachments. It is needless to say that no consideration should be shown except to relieve the hospital of its incubus. Too lengthy treatment is not always best for these cases.

Our Argus eyed inspectors at the very foot of Liberty's statue bid fair to give an account of the undesirable classes from abroad, but the State has done such wonders with its maternal care and coddling that the hospital is now a veritable *hospice* toward which is directed any and everybody who shows the slightest aberration. The policeman marches the mumbling rounder promptly to the nearest reception hospital, and an alacrity is always shown by interested parties in diverting to us the harmless old mendicant prayerfully haranguing the sun, while the profane and lusty tramp of violent speech, begotten of frequent ejections, is especially the object of their solicitude and, incidentally, of State hospital care.

The question arises, Do we check the flow at the fountain head, or are we content merely to exhibit *vis inertia* and receive the flotsam and jetsam

brought to us by the scores of small streams, scavengers of the country side? The flood comes from the supply already domiciled here. If it was dependent only upon foreign supply, we could easily avoid the consequences by demanding a certificate of sound mental health at the port of entry or, if necessary, at place of embarkation or, to reach out still further, from the native town or village of each immigrant.

But our asylums are not filled by the sharply challenged immigrant, who is not always as black as he is painted, and we have a knotty problem to solve in devising a way to check the increasing stream of insanity of all degrees and stages. After a long association with the classes received at probably the largest hospitals for the insane in existence, I can but conclude that the remedy must be applied before the patient is submitted to the examiners in lunacy.

Theories and opinions, fortified by new classifications and further buttressed by many a foreign *ipse dixit* of academic soundness, give rise to very agreeable and interesting scientific discussions, but they lessen the incoming tide, or relieve the hospitals of their burdens, not one jot. Our patients come, we must agree, from the field, the factory, and the office, and must, as a matter of course, in the large majority of cases come first to the notice of the family doctor. Therefore, to the general practitioner, and not to the trained alienist, must we look to relieve us of our increasing burden. That he has been more or less delinquent in this respect is apparent to us all, for who of us has not been frequently impressed by the shameful neglect of proper medical treatment for patients prior to their commitment to a hospital for the insane?

To minister to a mind diseased is perhaps not the daily routine of the general practitioner, but he will find scores of incipient cases in his daily rounds whose progress he can arrest, and the responsibility rests upon him to guide the patients into a safe haven. The physician could do an immense deal of good to his patients and to the hospitals if he had a better knowledge of the nature and phenomena of mental disease. We see, every day, patients arriving who, if taken in time, need never have sought the protection of a certificate of insanity. We see case after case showing toxæmia following abeyance of function, the result of too close application and overwork amid insanitary surroundings. Such cases, taken in time, unquestionably would have responded to proper medical treatment. Hundreds of patients are committed to our asylums yearly, a large portion of whom have the conviction that they need never have been certified as lunatics had they received timely medical advice in the stage of incu-

bation, and their functions and physical condition bear them out in their lamentable statement of neglected health.

The medicine of the future will be largely one of prevention of disease, insanity in particular, and the preservation of health. The general practitioner should exercise vigilance and should be urged to stop the downward course, and the subsequent filling-in of asylums. If a man is obviously a lunatic, is suicidal or dangerous to others, he should properly be placed in a hospital for the insane, but such a place is not for cases of neurosis or exhausted states due to neglect or lack of medical care. The family doctor is the first to see the cases in the stages in which alone the disease is curable. Many of these patients can be treated at home and cured.

In his daily rounds the practitioner sees the departure from normal health in a hundred forms. He has the opportunity to check its progress and give sound advice, and can manage to see every member of the family at one or other of his visits. The parents or some of the family can be encouraged to confide in him regarding the mental condition of any one of them and by treatment for the declining bodily health upon which it depends the patient can be restored in mind and body. The working classes should be taught to seek a physician's advice much more frequently than they do. It might be brought home to them through their pockets if in no other way, for the dullest intellect will comprehend that the weakling cannot bring grist to the mill, and that fact being impressed, the doctor undoubtedly will be called in without delay.

In these days, when our social and economic systems are disturbed by disorganizing factors, industrial upheavals, and strenuous competition between those well and those poorly equipped for the struggle, a large number of old and young are to be found on the verge of physical and mental breakdown. They dare not give in, for the pace has been set, and they strain every nerve to respond to the demands. While able to drag along neither they nor their families will consult a physician. The laborer, in his ignorance of the laws of nature, sweats in the darkness. The workers in the factory and the slums; the professional man overconfident in his intellectual powers and well ordered nervous system; the lad at school weighed down by too close application and not enough open air exercise; the shy retiring boy just yielding to evil inclinations; the worried business man and father bearing a heavy load and seeing no way of lightening it—all these patients are very near the borderland of mental affection and this is the very time when proper medical advice could avert disaster. A large number, the condition recognized, if taken from their

work and sent to the sea or mountains, or even advised to do half time, could ward it off. The family doctor sees such cases every day.

The neurasthenic with trepidation consults his physician. The alcoholic with his fleeting delusions and the railroad man complaining of nervous exhaustion and fearing that his nerve is failing him are cases which require close watching. The mother with her dangers of the climacteric, bending under the monotonous drudgery of household cares, the young girl with her period of evolution, ungratified longings, and hypochondriasis, and the man who has his sleep broken and begins to hear voices at night demand medical attention. This is the period of initiation and incubation. These are the varieties of ailment becoming insanity. This is the doctor's golden opportunity. A few days in bed with "rest" treatment, and perhaps nothing more is required. A short time in a general hospital or under observation would enable a large number to clear up sufficiently to resume work and the care of family, the physician's advice helping along to recovery.

Thirty per cent. of admissions to hospitals for the insane are cases due to neuroses, drug and drink habits, toxæmias of adolescence, and states incident to the menopause. A few days off the farm and the carking cares of the house, and the results will be astonishing if the doctor shows determination to nip the symptoms in the bud.

An early diagnosis is of the utmost importance, and the adviser has a boundless opportunity to check the downward course by sending his patient away, even in the face of a threatened poverty, which is preferable to certain poverty with the additional burden of the sick or insane father or brother. The inclination to send to the medical certifiers should be resisted to the last. It should always be the *dernier ressort*. An asylum is not by any means the best place in the world for him; it is not the solution of the problem. Comparatively few require such extreme measures as being locked up from family and consigned to the discipline of an institution for the insane with the loss of personal liberty and dissolution of family ties. A timely word to the patient, a hint to the family, even if it is unheeded, and there is time to defer this regrettable action. Send him abroad if his circumstances permit, or to the sea or mountains. For those long immured in the country the diversion of a densely populated city may be beneficial, but not the discipline and rules of an institution.

The overcrowding of State hospitals has become a necessary evil through the ready complaisance in writing out a certificate of insanity, and many have been taken to asylums against their will, their families inflicted with horrible doubt, and the patients themselves subjected to suspicion ever after-

ward. It is true, although to be deplored, that the knowledge of a former asylum residence militates seriously against a man, for there is always a doubt about his mental restoration. The pilot experiences difficulty in getting back his old post, the engineer may obtain sympathy, but seldom the charge of his train or yacht, and the business firm is decidedly averse to placing responsibility in the hands of a man with an asylum history.

No one appreciates this handicap more than the patient himself and, therefore, he does his best to keep the fact of failing physical or mental strength concealed when his daily bread is at stake. Proper and early recognition by the doctor may enable the patient to avert what must be a blot upon him for the remainder of his days, while under proper medical supervision he would be infinitely happier outside asylum walls.

If the physician will pay less attention to the mental condition and treat the failure of bodily health upon which it depends, for he should know that functions are not slow to become disordered, he frequently may effect a recovery in mind and body. Indeed, many most unpromising cases benefit so much by change of scene and occupation that they scarcely would be recognized as having narrowly escaped the restrictions of a hospital for the insane. Every day it is more forcibly impressed upon us that a large number of cases of degeneration can be arrested before becoming fully developed.

The care of fully established cases of insanity is not in question. Such should go to the alienist, but the physician has it in his power to prevent the full establishment of insanity. He can shed light upon the darkness begotten of ignorance regarding syphilis and its inclusive list of general paralysis, tabes, and all the disastrous consequences to immediate sufferers, including the neuroses of degeneration resulting from it. He has it in his power to assist the asylums and benefit his patients who time and again lament the fact that they received no medical attention before admission. Their friends, when questioned, admit that no physician was consulted until pronounced mental symptoms were exhibited and the patient became unmanageable.

The school curriculum in each practitioner's neighborhood may well arouse his concern, its absurdly high standard being frequently out of all proportion to the mental and physical strength of the pupil. He may see many a growing and promising lad whose precocity is mistaken by his proud parents for unusual mental endowments, winning prizes and scholarships at the ruinous price of his mental and physical stamina. The writer has seen such cases end in complete bodily wreck, mental enfeeblement, and frequently complete dementia,

rendering the subjects fit only for an asylum for the rest of their days.

That the family doctor can do much for us if he cooperates heartily is brought home by the astonishing length of time some discharged patients, not considered favorable cases, remain at large when placed under his surveillance. There is no doubt that the *facilis descensus* of the defective and the delinquent, with the resultant crowding of asylums, can be materially relieved by the efforts of the family physician.

INGUINAL BUBO AS A COMPLICATION OF MALARIAL FEVER. ADDITIONAL REPORT.

By A. C. SMITH, M. D.,

NEW ORLEANS,

SURGEON, UNITED STATES PUBLIC HEALTH AND MARINE HOSPITAL SERVICE.

In the *New York Medical Journal*, for June 22, 1901, I reported a short series of cases of what I believed to be inguinal bubo accompanying and caused by malarial fever. Unfortunately I was not able to demonstrate the character of the fever beyond doubt by the results of blood examinations. Since that time I have been looking for other cases to confirm the diagnosis, but not until I reached the Gulf States again did I see a typical case which presented an opportunity to demonstrate the theory.

In the case which is reported herewith the proof appears to be clear and sufficient. The patient had recurring attacks of quotidian malarial fever. In one attack, the second treated by me, the inguinal glands became acutely tender and swollen with the onset of the fever. The plasmodium malarie was found in the blood. The fever yielded to treatment with quinine and arsenic and the bubo subsided also. The bubo and fever recurred, and again yielded to the antimalarial treatment. There was no indication whatsoever of any venereal disease as a possible explanation of the bubo. The detailed report follows:

F. F., aged, 23 years; place of nativity, Dutch West Indies; color, white. Admitted to hospital January 3, 1905, from a steamship in the Porto Rican trade.

The patient gave a history of having been sick for five days, with a chill and rise of temperature about noon every day and a sweat and decline of temperature about 7 p. m. A calomel cathartic was given and treatment with quinine was instituted immediately; the patient had a chill and rise of temperature the next afternoon, but no further attack, and he was discharged from the hospital January 12th.

February 24th he returned. At the time of his second admittance he gave a history of having been sick about seven days. The fever had re-

curred daily, but chills were at irregular intervals. A remarkable feature of the attack was that he felt pain and tenderness in both groins whenever he had a chill. At the time of admittance the glands in the right groin were scarcely swollen, but were sensitive to touch; the glands in the left groin were very perceptibly swollen, without induration, and quite tender; and he felt an aching pain in both groins. Tongue, moderately coated. Bowels, inactive. Lungs, apparently sound. First sound of heart, soft, like a hæmic murmur; apex beat, normally placed; rhythm, regular. No venereal history. A calomel cathartic and a placebo of compound tincture of cardamom were given.

An examination of the blood, made the afternoon of February 25th, revealed the presence of the malarial germ, tertian variety, in considerable numbers, with some irregularity in the size and shape of the red cells.

The patient had a very slight chill the morning of February 26th, and a moderate rise of temperature in the afternoon. The glands in the left groin became a little larger and firmer than before. Quinine was given first the morning of February 27th. The course of the fever was peculiar in that it rose and continued high for a number of days while quinine was being administered freely. The bubo, on the other hand, diminished in size rapidly. Warburg's tincture was given a part of the time instead of quinine sulphate; on March 8th both were stopped and treatment with arsenic was adopted.

On March 3rd, the malarial germ was still present in the blood, but in reduced numbers. From March 10th the patient's temperature continued practically normal, and on March 20th he was discharged as recovered. Two glands could then be felt in the left groin, slightly indurated, but not visibly enlarged.

On March 28th he came to the hospital again on account of a return of the bubo, which had become acutely painful and swollen three days before. He was not aware of having had a return of the fever, but his temperature was 37.6° C. the morning of admittance and rose to 39.8° C. in the afternoon. The glands in the left groin were large and tender, and two lumps could be distinguished by touch, rounded in outline and almost coalescing. Being satisfied as to the character of the fever I did not wait to examine the blood, but gave quinine immediately, at 10.30 a. m. An examination made at 5 p. m., six and a half hours after quinine was administered, failed to reveal the presence of the plasmodium malarie, but showed free pigment granules and hæmin crystals and some degree of leucocytosis.

On this occasion the fever yielded quickly to treatment, but the bubo subsided more slowly and there was considerable anæmia and debility. Arsenic had the best effect on the anæmia. The patient was discharged on April 24th; two very small indurated lumps could still be felt in the left groin, but he was feeling well and could not be longer held in hospital.

The condition of the blood found on this last occasion, with free pigment granules and some leucocytosis, but no discoverable plasmodia, was

such as I have found in a few other cases in what appeared to be a similar stage of this disease. I doubt that the plasmodium would have been found if the examination had been made before any quinine was administered.

Our Subscribers' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at regular intervals. So far as they have been decided upon, the further questions are as follows:

XXXIX.—How do you treat erysipelas of the face? (Answers due not later than June 15, 1905.)

XL.—What are your views on the obstetrical binder? (Answers due not later July 15, 1905.)

XLI.—By what honorable means may a young physician best promote his success in practice from the business point of view? (Answers due not later than August 15, 1905.)

Whoever among our subscribers (with the limitations mentioned below) answers one of these questions in the manner most satisfactory to the editor and his advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but NOT REQUIRED) that the answers be short; if practicable, no one answer to contain more than six hundred words.

Only subscribers to the NEW YORK MEDICAL JOURNAL AND PHILADELPHIA MEDICAL JOURNAL (including regular and volunteer officers of the Medical Corps of the United States Army, Navy, and Marine Hospital Service, commissioned or under contract) will be entitled to compete, and all persons known to be engaged in medical journalism are disqualified. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.

The prize of \$25 for the best essay submitted in answer to question XXXVIII has been awarded to Dr. James Stratton Carpenter, of Pottsville, Pa., whose article appears below.

PRIZE QUESTION NO. XXXVIII.

THE PREVENTION OF DISEASE OF THE VERMIFORM APPENDIX.

By JAMES STRATTON CARPENTER, M. D.,

POTTSVILLE, PA.

The personal factor in this question must determine the character of the reply. The question is not, How may appendicitis be prevented? but, How will you be governed in your efforts to prevent the occurrence of this too rapidly increasing disease of American life, one with which the laity is so familiar through repeated instances of its occurrence among them as to be able, in nearly every instance, to diagnose the disease before the physician who may have been summoned arrives upon the scene.

The popularizing of knowledge concerning any disease has some advantages, and we may derive valuable aid in the successful combating of the

particular disease under discussion by familiarizing the people with a treatment that shall be potent for good results when promptly availed of by them, while we may even hope, eventually, to prevent its occurrence by acquainting them with the best means of avoiding its attack. In other words, preventive medicine should be here, as in other directions, the great desideratum, not the needless subjection to the knife of the surgeon of every unfortunate sufferer with the classical pain in the right iliac fossa.

Were the question How may appendicitis be prevented? I doubt not it would be answered by the vast majority by "an early removal of the appendix." But our discussion of this question must be made with the idea of the greatest good for the greatest number, and I am of the opinion that a great deal of unnecessary mutilation is being undertaken nowadays by the surgeon, and many a life lost through the mistaken idea that surgery alone is able to save the life once threatened by the acutely inflamed vermiform appendix.

We are not asked to do more than provide our readers with the best means for the prevention of appendicitis, and so, not being concerned with the treatment of the inflammation, let us seek some vantage ground where we may find a common agreement, and then deduce some tangible expression of our thought that will, at least, be defensible on that basis.

I have referred to appendicitis as "the rapidly increasing disease of American life," and, I think, with sufficient reason. We do not find any country where the disease is more prevalent than in our own, or, I am sure, anywhere so frequent operations are undertaken for its cure. And, yet, right among us live a people who are so seldom affected by it as to make it of exceptional occurrence when a case of the disease appears among them. In a practice covering a period of twenty-four years I have never seen an attack of appendicitis in a negro; and while I have not had sufficient practice among that race to make the statement noteworthy, yet I have never thus far even heard of an operation for appendicitis being performed upon a colored patient. Howard Kelly and Burdon have made this fact prominent in their classical work on *The Appendix and Its Diseases*, but they have failed to go farther and evolve out of this immunity of the negro race from appendicular attacks the best means of its avoidance by the whites.

Now if we consider for a moment our modern civilization and the rush and hurry of this twentieth century living, to which the black is a com-

parative stranger by reason of his very inability to attain unto it, have we not a sufficient reason furnished us for his immunity, if out of the hurly-burly of his more favored white brother's existence we may extract good reasons for the latter's greater susceptibility to the disease? It would surely seem so. The rush and hurry of living—the pursuit of "the almighty dollar"—is the most plainly deducible cause for the existence of appendicitis based on the foregoing hypothesis. Stop a moment and compare the earlier days of the nineteenth with these present ones of this early twentieth century. Life then did not flow at such resistless speed as now; the stage coach of our ancestors and the automobile that now crowds our streets make two pictures that eminently portray the two epochs of our national life; and I do not think I should be liable to contradiction did I affirm that in those earlier times appendicular inflammation must have been almost as great a rarity as now we find it to be among those equally easy going, but more indolent creatures, the negroes.

If in a general way we may deduce that "a quiet life," with its regular performance of duties, freedom from nervous excitement, and securing of needed rest for wearied mind as well as fatigued body are factors in the prevention of disease of the vermiform appendix, how may we, more particularly, reach a conclusion that will sustain this thought? Surely a study of the anatomy of the appendix, the nervous and vascular supply, its peculiarly well adapted situation for attack, are not the only considerations to be borne in mind. These have existed for more than six thousand years, if our ideas of the creation of man are correct, while the terrors of appendicitis have announced themselves within a very recent period. No, we must take the disease itself into consideration, and we find at once, in an examination of its prominent symptoms, that *constipation*, existing both prior to and during the attack, is a most constant factor in its causation.

How may we prevent constipation? Solve this question, and we shall probably reach the desired preventive treatment for appendicitis. Shall we find its solution in the fervid life of today, the hurry and bustle of which leave us so little time for eating and sleeping that our bowels may take care of themselves as best they may? Too often is that call of nature unheeded or put aside for a more convenient season, and thus it comes that we find ourselves depending on laxatives and cathartics until, in one of those moments of masterly inactivity of the intestinal tract, the blow falls that, like the sword of Damocles,

has long been threatening, and after a particularly heavy meal, or a chill, or other exciting causes, the ideal conditions necessary for the appendicular attack are created, and the attack begins.

We are not overdrawing on the imagination surely. By no other race is existence maintained at so high a pitch as by the American people, and no people can live at such a tension without incurring the diseases incident to their neglect of Nature's laws. We stand aghast at what statistics are telling us of the rapidly increasing mortality from various diseases, and appoint our various learned commissions to penetrate into the mystery of it all; but "symposiums" and commissions are equally doomed to failure in their laudable efforts to withstand the progress of disease when they overlook the persistent wilfulness of man in rushing to his own destruction. Bring life down to a regular methodical living; set apart your hours for work, your times for eating and sleeping, as well as those for healthful, judicious exercise, and you will stand in no great need of special commissions for the study of disease, least of all of how to prevent appendicitis.

Dr. Gerald Bertram Webb, of Colorado Springs, writes:

By arranging the pathogenesis in the following order methods of preventing the causative factors can be concisely related:

1. *Digestive Disturbances.*—Educate children and advise patients in the proper methods of eating and drinking. Give careful attention to the teeth and proper mastication. Inculcate avoidance of hasty meals; warn against overeating; see that plenty of water is drunk and at proper times. Especially try to prevent the modern exhaustion of nervous energy, since neurasthenia is the cause of most digestive disarrangements. Advise rest after meals. Regulate the results of neurasthenia, such as flatulence, constipation, and improper and relaxed fecal evacuations, if possible without drugs; advocating rest, mechanical treatment, and diet. Should a drug be necessary, castor oil is the best, given every week or so to empty especially the contents collecting in the cæcum. Advocate generally a diminished meat diet. Remembering the comparative physiology and anatomy of the appendix I have not restricted patients in vegetables and fruits, but rather encouraged the use of these. I do not think the forbidding of all seeds necessary or practicable. Most of the fecal concretions found, being formed in the organ probably through faulty secretions and helped by bacteria and improper peristaltic movements of the appendix and by deviation of the

appendix, it does not seem to me that restriction of certain foods, in moderation, will prevent an attack, unless a previous attack has been felt by the patient to be due to some particular article. Prevent overindulgence in such articles as pop corn, peanuts, etc., which may start an enterocolitis.

2. *Trauma*.—One can only preach the avoidance of violent exercise, especially that which provokes violent contractions of the psoas or transversalis abdominis, to those who have had an attack, and yet who do not wish to part with the organ. To advise avoiding violent exercise for lads is not practical, yet perhaps this is an important factor in their greater liability than girls, as in thirty out of forty of Kelly's reported cases of death from traumatic appendicitis the organ contained concretions; the reply in the preceding section, which deals with the prevention of disturbances of digestion, partly answers this, i. e., prevent the concretions, which probably can be done by proper attention to mastication and digestion. Floating kidney, in women especially, may be a traumatic agency, and should be attended to surgically or by the application of a proper corset or belt. Blows on the abdomen should be avoided. Belts and corsets, if worn at all around the waist, should be loosely brought together.

3. *Cases Arising Through Contiguity with the Female Pelvic Organs*.—Teach girls how to take care of themselves at the physiological period. Correct misplacement. Remove growths which may irritate the appendix.

4. *Exposure to Cold*.—When this cannot be avoided, and patients are susceptible in their entrails, the cholera belt or flannel band is of use. Encourage clothing which keeps the extremities warm.

5. *Enteroliths, Foreign Bodies, Entozoa*.—Enteroliths probably chiefly arise from digestive disturbances, faulty innervation perhaps being the starting point, through altered secretions from the appendicular mucous membrane (perhaps some antiperistalsis) encouraging bacterial growth. The prevention of this improper innervation has been considered. Teach children never to place foreign bodies in the mouth. Should they by accident be swallowed, administer a meal promptly of chopped up worsted in mashed potato, and follow some hours later with castor oil. Administer the appropriate remedies when entozoa are recognized, and since a large percentage of children entertain these unbidden guests, occasional doses of calomel and santanin or other vermifuges are wise, even should the worms not have proclaimed their presence.

6. *Rheumatic Fever*.—The salicylates and salol are especially valuable, and prevent the growth of bacteria which might instigate an attack. The best preventive treatment would be to see that patients were abstemious in meat, indulgent in water, took exercise, and took sweat baths.

7. *Infection*.—The pathogenic germs, such as the *Bacillus coli communis*, etc., can possibly be limited by prevalence of plenty of bile in the intestine, by the avoidance of digestive upsets, which help their thriving, and by the occasional administration of salol, calomel, etc.

In general, in those who have had one attack, the removal of the organ should be advocated. Remove the organ with the patient's permission when performing any abdominal section. Since it seems impossible to prevent the nervous digestive disturbances caused by the demands on the nervous system of strenuous competition, the time may soon come when removal of the appendix may become as familiar an operation in childhood as circumcision, especially in those whose progenitors have been victims.

Dr. Frank C. Henry, of Perth Amboy, N. J., writes:

It is presumed that Nature so constructed the vermiform appendix that in a healthy condition it possesses the function to relieve itself from inert masses or bodies that find their way into it. We must therefore attribute the initial cause to some interference with this normal function. And the cause that suggests itself is some catarrhal condition. I believe the initial lesion in appendicitis occurs most commonly in childhood. I base this opinion on post mortem work and general practice, also some experience in operating. In operating in some twenty-five cases of appendicitis, I was able to prove the initial cause in only two cases, and the cause in those cases was oxyurides. In the last case of operation in the Perth Amboy City Hospital, in November, 1904, I found about fifty oxyurides in an appendix about ready to suppurate. The other case I reported in the *New York Medical Journal*, for June 11, 1903.

I believe the reason surgeons do not find oxyurides more frequently is that they do not operate in the primary attack, or at least not until suppuration has taken place and the oxyurides are destroyed, and that in some cases the oxyurides are overlooked. From my own experience I know oxyurides do cause appendicitis, and knowing how commonly oxyurides occur in childhood, the wonder is with me, not that we have so much appendicitis, but that we do not have more cases. My preventive treatment for disease of the vermiform appendix therefore may be said in a few

words: Rid children and adults of oxyurides promptly.

Dr. C. Floyd Burrows, of Syracuse, N. Y., writes:

When considering the prevention of disease of the vermiform appendix it is well to remember that this organ is a relic of primæval man—an ancient warrior, so to speak, in a company of more modern and vigorous tissues—and that in repelling the invasions of bacteria from the territory of the cæcum it easily falls a prey to their attacks. Therefore the abdominal tissues of which it is an intimate member, and which influence it for health or disease, must be kept up to their best possible point of efficiency to protect it from bacterial advances. By producing abnormal conditions in the intestinal canal, and the cæcum in particular, indigestion and constipation stand as foremost factors in the causation of disease of the vermiform appendix. To prevent appendicitis, then, in many cases means the correction of alimentary disorders. Regularity as to feeding hours must be exacted; food must be eaten slowly, chewed fine, and never bolted or washed down with swallows of water, etc. Eating between meals must be absolutely prohibited, also the ingestion of pastry, candy, and nuts. Only easily digestible foods, like milk, meat, eggs, bread, and vegetables, are permissible. Dinner ought to be taken in the middle of the day, and a light supper at night. Eating just before going to bed must be positively forbidden. Overeating especially means gastric and intestinal indigestion, and should be cautioned against. Tea, coffee, malt and spirituous drinks, and the use of tobacco should be reduced to a minimum. Plenty of water ought to be drunk in the intervals between the taking of food, and a glass or two only allowed with each meal. Whenever quantities of gas collect and pain or distress occurs in the abdomen after eating, or any tenderness is perceptible in the right inguinal region, a brisk purge of magnesium sulphate or castor oil should be ordered to be taken at once and an ice bag or coil applied to the painful or tender area.

The bowels should be trained to move at a regular hour each morning, and a day should never pass when a movement is not obtained; if not naturally, then by the ingestion of a saline, cascara, or calomel, or else by a rectal injection. Straining at stool, however, must be absolutely forbidden. Careful attention to the daily movement of the bowels, intelligently carried out for a proper period, will correct nearly all cases of constipation, if associated with careful dieting and feeding. Calisthenics and abdominal massage may also assist. Outdoor exercise of various

kinds, particularly walking and horseback riding, is also very beneficial in the regulation of indigestion, and thus helps to prevent disease of the appendix.

Traumatisms and strains, next to alimentary disorders, are fertile causes of appendicitis; consequently too vigorous athletic pursuits, the lifting of heavy objects, strenuous bicycling, or straining or tugging in whatever fashion must not be permitted at all. The relation of the appendix to the psoas muscle must be considered, and movements which bring this into violent contraction avoided.

The appendix is made up largely of lymphoid tissue, and, like the tonsils and Peyer's patches, it is subject to inflammation along with these in gripe, rheumatism, scarlet fever, and typhoid fever. Therefore it is wisdom in every case which presents hypertrophy of the tonsils and adenoids to advise special care in the avoidance of those diseases. In gripe and rheumatic attacks early treatment with sodium salicylate and alkalies, rest, and careful feeding, with attention to the bowels, are to be advocated. Not much can be done in scarlet or typhoid fever or general bodily infections of other types to prevent involvement of the vermiform, except the careful treatment of these diseases along their respective lines. Special care should, however, be taken about feeding, the state of the bowels, and the reduction of tympany.

In women menstruation is an exciting feature also in the causation of disease of the appendix. The menstrual periods should be guarded from anything which increases the congestion of the internal generative organs, such as exposure to cold, coitus, douchings, etc., and the flow should be encouraged by hot drinks and foot baths. Rest and freedom from work and exercise are also to be advised.

Foreign bodies play a small part in the rôle of causative agents in appendicular disease. Pins are foremost in the list of objects which sometimes find their way into this organ. Shot and pieces of lead, bones, hairs, fruit, seeds, gallstones, and intestinal parasites are each sometimes found present. Care, then, should be exercised never to place a pin in the mouth, also in the eating of game or canned food, fruits, meats, etc., that the objects mentioned are not carelessly swallowed. In patients who are afflicted with worms the parasites should be removed by the usual therapeutic methods without delay. Gallstones may also be removed by surgical means if they are passing the bowels in sufficient quantity to cause concern.

Little can be done to prevent disease of the appendix in persons predisposed to it by anatomical deformities, malpositions, concretion formation tendencies, or extension of disease from contiguous tissues. Floating kidneys, however, may be sewed in place and pressure relieved, and diseased Fallopian tubes and diseased ovaries removed.

I believe it advisable, whenever the abdomen is opened surgically and conditions permit, to remove the vermiform appendix whether it is healthy or not. This is certainly one sure preventive of disease of this organ.

(To be concluded.)

Therapeutical Notes.

The Transformation of Theobromine Into Formic Acid.—M. L. Serbource, in *Bulletin commercial*, for April 30, 1905, comments on the communication of Dr. Huchard, which appeared in *L'Union pharmaceutique*, for March 31, 1905, page 129, as follows:

If by clinical observations Dr. Huchard has found a certain analogy between the therapeutic effects of formiates and those of theobromine, chemistry, according to my modest experiments, will corroborate him, since by simple oxidation *in vitro*, I have transformed theobromine into formic acid. I intend to publish in a short time the result of my work, and it is only to assert my right of priority that I recapitulate my conclusions.

It is known that caffeine, as well as theobromine, oxidized by an indirect agent (chlorine or bromine), is transformed into alloxantin—

which produces with ammonia, ammonium purpurate, or murexide—this is, in fact, the characteristic reaction of these two alkaloids.

I have found, however, that caffeine and theobromine, oxidized by direct agents, instead of producing a uric acid derivative are transformed into formic acid.

Almost all the direct oxidizing agents effect this transformation,¹ but the most easily handled is ammonium persulphate.

If, for example, one part of theobromine with three parts of ammonium persulphate and about ten parts of water are warmed, an active effervescence ensues, the liquid becoming limpid, and the theobromine transformed. It is only necessary to allow it to dry and then wash with alcohol to obtain crystals which may be identified by the following reactions: (1) Complete volatility; (2) formation of a mirror by boiling with silver nitrate; (3) transformation of mercuric chloride

into protochloride; (4) odor of rum by boiling with alcohol and sulphuric acid.

The salt obtained must be ammonium formiate.

The same procedure may be repeated with caffeine and the same results obtained. There is, therefore, no reason to wonder at an analogy between the therapeutic properties of the formiates and those of theobromine.

The Diuretic and Tonic Actions of Formic Acid.—At a recent meeting of the Academy of Medicine, of Paris (*Répertoire de pharmacie*, April 10, 1905), M. Huchard recalled that for two centuries formic acid had been employed as a remedy under the name of *eau de magnanimité*. It appears still in the German Pharmacopœia. In 1904 Dr. Clément discovered the tonic action of this acid on the muscles. M. Huchard has observed that this action makes itself felt on the unstriped as well as the striped muscles. Formic acid can be of real service in neurasthenia, diabetes, and in the various stages of adynamia and senile weakness. It can also be used to overcome fatigue on long journeys. Formic acid acts as a diuretic, its action being, however, inferior to that of theobromine, but it has the advantage of diminishing the quantity of albumin. It can, therefore, be employed, according to M. Huchard, in the treatment of arterial cardiopathies. It is non-toxic and does not irritate the stomach. Potassium formiate, which is perhaps more diuretic, is prescribed, but sodium formiate is more frequently used, the salt being administered in doses of 3 grammes daily. Lithium formiate may also be prescribed, but in a smaller dose (1 to 1.50 gramme daily). The following is a good formula: Syrup of bitter orange peel, 200 grammes; sodium formiate, 10 grammes. Dose, one tablespoonful three times a day. Usually this medicine is taken for ten days, with an intermission of six days, and so on for several weeks and even months. M. Huchard regards sodium formiate as an efficient therapeutical agent of the future.

Some of the Uses of Oxidized Pyrogallallic Acid in Dermatology.—Jamieson, in the *Edinburgh Medical Journal*, for May, 1905, refers to Unna's investigations with pyrogallallic acid and to the advantages of its derivative pyraloxin. Unlike pyrogallallic acid pyraloxin has no toxic properties, seldom excites dermatitis, and is recommended for the treatment of psoriasis and leprosy, and also lupus erythematosus and eczema palmaris. For psoriasis it stands next to chrysarobin in efficiency, and in some cases it is even superior to it, this being especially the case when there is retrogression of the disease. It is one of the best external remedies for lichen planus, relieving the itching and favoring the disappearance of the eruption. Though it is useful in lupus erythematosus, it leaves a deep black stain upon the tissues. In infantile eczema of the face pyraloxin may be added with advantage to Lassar's paste. In staphylogenic sycosis it may be applied after the hairs have been removed by x rays. For ringworm of the scalp in children it is also beneficial, destroying the fungous elements which have become located in the skin.

¹ Schmidt has already proved that formic acid is a product of numerous compounds formed when hydrochloric acid reacts on theobromine. Formic acid is found also among the products of the action of baryta water on theobromine.

NEW YORK, SATURDAY, JUNE 3, 1905.

TYPHOID FEVER AS A SCOURGE OF ARMIES.

Taking as its text the comparative exemption of the armies of Japan from disease of a deadly nature during the campaigns against the Russian forces, and properly according precedence to typhoid fever among the diseases that persistently cripple European and American armies, the *Lancet*, in its issue for May 20th, seeks to account for the insignificance of that disease as a destroyer of Japanese soldiers during the war now in progress. Our contemporary's reflections are almost wholly of a suggestive, not to say speculative, character, though it lays some stress on the proposition that typhoid fever is not an exclusively water borne disease and on the consequent deduction that the Japanese practice of isolating such soldiers as may contract it is rather powerfully contributory to its restriction to the minimum.

It seems to us that this isolation, in conjunction with measures that would naturally go with it, would be quite sufficient, irrespective of the question of whether or not typhoid fever is spread by water alone, to effect a material reduction of the typhoid morbidity; but the *Lancet* goes further and suggests either that the Orientals have largely acquired immunity by having had the disease in childhood or that they enjoy an immunity derived from the nature of their food, in which vegetable substances predominate. It appears to incline to the

theory that the virtual elimination of meat from the diet is adequate to account for a degree of immunity which it supposes to exist among the Orientals, but it remarks that typhoid fever is really much more prevalent among the natives of India than had until recently been supposed. The only significant fact adduced by our contemporary in support of the vegetarian theory of immunity, it seems to us, is conveyed in this statement: "The cases of typhoid fever which do occur in the native (Indian) army are mainly among the Gurkha troops, who are meat eaters and spirit drinkers." Perhaps this may be explained on quite another supposition than that the bacterial flora of the intestinal canal in vegetarians may be held to be substantially different from the corresponding flora in the omnivorous, as the *Lancet* suggests.

We are disposed to attribute the comparative freedom of the Japanese armies from typhoid fever to their admirable sanitary arrangements rather than to any racial or dietetic immunity. The government of Japan seems to have been wise enough to commit the health of its armies into the hands of its medical officers without trammel, and other governments, including our own, would do well to follow its example. It is futile to think of inducing our people to subsist on rice or on any exclusively vegetable diet, and to argue that such a diet may possibly prevent typhoid fever will never save an American or an English army from devastation by that disease.

THE INSANE IN THE STATE OF NEW YORK.

Whoever is in danger of underrating the importance, the magnitude, or the varied character of the problems connected with the care of the insane in so large a community as that of the State of New York is likely to be set right if he will read the *Twelfth Annual Report of the State Charities Aid Association to the State Commission in Lunacy*, recently issued. It is fortunate for the insane that such an enlightened organization is influential in their management.

It appears from the report that on October 1, 1904, there were 25,019 inmates in the fourteen regular State hospitals, 844 in the two State hospitals for the criminal insane, and 998 in the twenty-three licensed private asylums, making a total of 26,861,

a number greater by 927 than the total at the corresponding date in the preceding year. Probably this increment represents approximately the annual increase of insanity in the State. In spite of the present rigid inspection to which immigrants are subjected, it is not unlikely that much of the increase is due to the landing of insane persons from foreign countries. Though in this matter as in all others the State of New York has to bear the brunt of the evil of undesirable immigration, the association does not think it wise for the State to undertake to supplement the national inspection service.

The prospective establishment of a reception hospital for the insane in the city of New York, authorized by recent legislation, is highly favored in the report. "It now remains," we read, "for the city of New York to do its share toward the establishment of this hospital by acquiring by purchase or otherwise sufficient and suitable lands conveniently located within the borough of Manhattan." Such a hospital, it is properly pointed out, would furnish a timely refuge for persons whose mental impairment might be only temporary if they could meet with appropriate treatment without the delay incident to a formal commitment; would, by its outpatient department, accomplish a great deal in the home treatment of individuals in danger of lasting insanity; and would furnish opportunities far superior to those now available for the clinical teaching of psychiatry.

The report deals with many other features of the work of caring systematically and humanely for the insane, but we have not space for their consideration at present. We cannot, however, refrain from expressing our gratification at the appreciative terms in which the report speaks of Dr. Peterson and Dr. Macdonald, who recently resigned, the one from the State Commission in Lunacy and the other from the superintendency of the city asylums.

EPILEPTIC STUTTERING.

It is well known that stuttering is often accompanied by convulsive contortions of the face, also that in some instances convulsive movements of other parts of the body are evoked by the stutterer's attempts to speak. It is known, too, that epilepsy and the stuttering defect of speech may both affect an individual without any manifest

connection with each other. But it seems to be true that in certain cases there is a relation between stuttering and epilepsy. The relation varies in different instances, and some of the variations have lately been made the subject of an interesting article by M. Féré, of the *Bicêtre* (*Revue de médecine*, February).

Sometimes, says M. Féré, habitual stuttering is intensified after an epileptic fit, or a recrudescence of the defect of speech may be the only manifestation of an epileptic crisis, the actual convulsion and loss of consciousness failing to appear. More rarely it is only in connection with an epileptic paroxysm that the stuttering occurs, preceding it, following it, or taking its place, in which last mentioned case it is a true manifestation of epilepsy and deserves to be ranked as such. When stuttering follows an epileptic attack, it should be looked upon as a continuation of the nervous discharge or as a result of the exhaustion consequent upon the paroxysm.

When stuttering precedes the attack, it is the first manifestation of the storm. The time intervening between its onset and the beginning of the convulsion may be so brief that it may be regarded as an aura; in other instances it serves as a warning, occurring some minutes or even hours before the convulsive attack, and it may not continue up to the time of the fit. Attacks of stuttering that really replace the ordinary epileptic paroxysm are apt to be misinterpreted, but, on the other hand, they are sometimes so characteristic that the patient himself recognizes their significance.

SENILE AND INFANTILE OSTEOMALACIA.

By the term osteomalacia is meant a disease involving the osseous tissue in general and characterized by true decalcification of the skeleton. In some cases the process may be localized in the neighborhood of foci of suppuration, at least in osteomyelitis, as has been shown by Gayet and Bonnet. But generally speaking the softening is very extensive. In the adult the disease more frequently attacks women, and the affection arises after several pregnancies, although it may occur in the nulliparous. Osteomalacia is exceptional in the male and makes its presence known,

in the first place, by pains in the limbs and in the ischiadic regions. Then deformities arise, due to the curving of the diaphyses, while the exaggeration of the patellar reflexes and generalized hyperæsthesia indicate the great excitability of the nervous system. There is also a very marked elimination of the urinary phosphates, and from this arises the decalcification of the skeleton, which later on will be made evident.

In children, as in elderly people, certain changes appear in the clinical picture, giving rise to diagnostic difficulty. In the child osteomalacia is by no means frequent, but it has been met with between the ages of eight and ten years. One rarely meets with an absolutely pure type of the affection, and the process is more frequently accompanied by a more or less pronounced rachitic process. Koenig has given a very distinct clinical picture of the disease in the young, and he points out that the beginning is very slow and insidious, while some few digestive disturbances, such as anorexia or diarrhœa, make their appearance. The little patients lose flesh and soon pains in the legs, which are deep seated and diffused, draw the physician's attention, and at the same time one notices that the patient presents an exaggerated susceptibility, insomnia, and agitation. Temporary contracture of the adductors and extensors appears, and these muscular disturbances soon give rise to a peculiar gait, very similar to that of a duck.

The bone changes then make their appearance; the height of the subject decreases and an arrest in growth takes place. The diaphyses become misshapen and bent, the deformity arising in the lower limbs in the first place. The muscles of the limbs become atrophied, and such changes easily explain why fractures arise from the slightest cause, while repair takes place badly or not at all. Broca has pointed out the frequency of genu valgum; the epiphyses are markedly thickened, and on palpation the bones feel like pasteboard. Radiography shows in a most distinct way how poor the bones are in mineral salts, because the shadow is hardly darker than that of the cartilages. Occasionally one meets with a frequent deformity in rickets, craniotabes, that is to say, a thinning of the bones of the skull which gives

rise to the feeling of pasteboard or a thin metallic plate, met with particularly over the parietal and occipital bones. The course of this disease is both continuous and progressive, lasting from eight to fifteen months, and death is the ordinary outcome. When a fatal issue does not occur, because energetic treatment may occasionally put a stop to it, the patient is the possessor of a fragile skeleton and is always exposed to a recurrence of the disease.

The diagnosis of osteomalacia in children presents little or no difficulty, although in the first place one may be more inclined to look upon the condition as one of rhachitism, but in the latter the child, from the very beginning, never presents the pains met with in osteomalacia or the nervous susceptibility which is common to the former affection. Later on in the evolution of rickets, the deformity arising in the diaphyses is less pronounced and the swelling of the epiphyses far more marked. However, the diagnosis will still remain difficult and frequently quite impossible to make. In hereditary syphilis of the bones a mistake in diagnosis is also possible, but the osteocopic pains are more marked at night, while the contrary is true of the pain in osteomalacia.

In elderly subjects one may meet with osteomalacia, but the general characters of the affection differ somewhat. The patient is usually a woman and complains, in the first place, of pain seated in the dorsal region, usually in the form of a pricking sensation or cramps, and not in the lower limbs as is the rule in children. One is apt to think of ordinary rheumatism, in the first place, and Piérart believes that nervous impressibility may be the cause of the pains; contracture, however, is exceptional in elderly subjects. The patients continue to walk and usually end by fracturing the tibia while going down stairs. In the case reported by Piérart, there were no changes in the reflexes and trembling was absent. In elderly subjects the urine does not always show evidence of an increase in the elimination of the phosphates, and even if it should contain them in excess this might simply be the result of treatment, because phosphatic preparations are taken internally.

Fractures are usually the first thing to draw

attention to the condition of the bones; the latter have no tendency to recover by the formation of callus, and consequently pseudarthroses result. Besides fractures, no deformity in the osseous system can be found, but the patients notice a sudden decrease in their height, due probably to the flattening of the vertebral bodies. The spinal column may take on an S shape or the back may become vaulted, but changes in the pelvic bones are rarely met with in elderly people. However, if the latter and those of the limbs show no change in their shape, the same cannot be said of the changes found on pathological examination. Under these circumstances they appear softened and friable, while their proportion of mineral salts is greatly diminished. The cranium shows no microscopical changes, but Piérart insists on the fact that a histological examination will show both the lesions of osteomalacia, namely, transformation of the osseous tissue into fibrous tissue with the presence of myeloplaxes, and osteoporosis; in other words, a pure and simple rarefaction of the bone tissue.

As in the child, senile osteomalacia shows a progressive evolution, and the treatment is not so effective as in the young, usually remaining without any results. The treatment should be prophylactic above all, consisting in a fortifying diet containing large amounts of phosphates, and in placing the patients in the best hygienic condition possible. When the disease has fully developed, rest, combined with the internal administration of the phosphates in various forms, will combat the disturbances of the general nutrition. In cases of fracture in osteomalacia, suture of the fragments has been recommended by some operators.

CHARLES GREENE CUMSTON.

A MEDICOLEGAL ASPECT OF X RAY STERILITY.

Destruction of the procreative capacity by means of applications of the Röntgen ray may perhaps prove of frequent occurrence if the use of the apparatus by anybody and everybody continues to be permitted. The matter was brought up by M. Hennecart at the Röntgen Ray Congress recently held in Berlin (*Presse médicale*, May 13th). He advocated legislation restricting the use of the ray on human beings to physicians, arguing that it would be difficult to punish laymen in the event of avoidable injury. He met

with hearty support in his contention, and, on motion of Dr. Becher, of Berlin, a resolution was adopted calling upon physicians to employ only medical men in x ray work, pending legislation on the subject.

MOTOR CARRIAGE FRACTURES.

Perhaps it is not with unmingled regret that we may look upon some of the performances of the motor carriage. It seems that the chauffeur is exposed to certain injuries of the forearm, especially at its lower portion, produced by a recoil of the crank when the motor is started. Two examples are recorded by C. Deutschländer (*Zentralblatt für physikalische Therapie, Diätetik*, etc., January; *Zentralblatt für Chirurgie*, May 13th), both fractures in the epiphyseal region, one of them attended with much overriding of the fragments.

OPHTHALMOLOGY IN PARIS.

An institution for the care of the eyes of the poor, founded by Baron Adolph de Rothschild, was opened in Paris during the week ending on May 6th. It is not surprising to learn from the cabled news that the hospital was opened without ceremony until we read further that it is the first one of the kind in the French capital. That so distinguished a scientific centre should have hitherto gone without a hospital devoted to this immensely important branch of surgery seems incredible and we should like corroboration of so astounding a statement.

THE EMMET DINNER.

The dinner given at Delmonico's last Monday evening, in celebration of Dr. Thomas Addis Emmet's seventy-seventh birthday, was even more largely attended than had been expected, and an enthusiastic spirit prevailed. In the formal toasts the various phases of Dr. Emmet's activities were specified, his career as a surgeon, his contributions to history, his achievements in art, etc. The proceedings constituted a well merited tribute.

The American Gynecological Society.—The annual meeting, held in Niagara Falls last week, proved to be one of the most satisfactory of recent years. Officers for the ensuing year were elected as follows: President, Dr. R. M. Maury, of Memphis, Tenn.; vice-presidents, Dr. Howard A. Kelly, of Baltimore, and Dr. Reuben Peterson, of Ann Arbor, Mich.; secretary, Dr. J. Riddle Goffe, of New York; treasurer, Dr. J. M. Baldy, of Philadelphia; member of the council, Dr. E. C. Dudley, of Chicago. The next meeting will be held in Hot Springs, Va.

News Items.

Society Meetings for the Coming Week:

MONDAY, June 5th.—New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vt., Medical Association; Hartford, Conn., Medical Society; Chicago Medical Society.

TUESDAY, June 6th.—New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson, N. J., County Medical Society (Jersey City); Androscoggin, Me., County Medical Association (Lewiston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, June 7th.—New York Academy of Medicine (Section in Public Health); New York Genitourinary Society; Harlem Medical Association of the City of New York; Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond, N. Y. (New Brighton); Penobscot, Me., County Medical Society (Bangor); Bridgeport, Conn., Medical Association.

THURSDAY, June 8th.—New York Academy of Medicine (Sections in Pediatrics and Otolaryngology); Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; Medical Society of the County of Cayuga, N. Y.; South Boston, Mass., Medical Club (private); Pathological Society of Philadelphia; Church Hill Medical Society of Richmond, Va.

FRIDAY, June 9th.—Brooklyn Dermatological and Genitourinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, N. Y.

SATURDAY, June 10th.—Obstetrical Society of Boston (private).

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending May 27, 1905:

	May 27.		May 20.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	888	19	769	10
Diphtheria and croup.....	331	26	345	36
Scarlet fever.....	184	15	201	13
Smallpox	1	1
Chickenpox	141	..	152	..
Tuberculosis	470	103	419	155
Typhoid fever.....	32	4	23	9
Cerebrospinal meningitis.....	76	60	99	72
	2,116	287	2,000	296

The Flag at Flushing Hospital.—The handsome American flag presented to the Flushing Hospital and Dispensary by the women of the Adam Wirth Relief Corps last February, was raised on Decoration Day for the first time on the hospital grounds with appropriate exercises. The ceremonies took place shortly after 8.30 a. m., and in attendance besides the members of the Hospital Board of Trustees were the cadets of Kyle Institute, all of whom participated in the exercises.

Vacancies in Bellevue Hospital.—There are at present three vacancies in the out patient department of Bellevue Hospital, two in the genitourinary clinic, those of first and second assistants to the surgeon in charge, and one in the general surgery clinic as second assistant to that class. Appointments to these vacancies will shortly be

made by the board of trustees of Bellevue and Allied Hospitals, and the board will be glad to consider the names of all desiring to present themselves as applicants for the positions. J. K. Paulding, secretary, board of trustees.

The Methodist Episcopal Hospital Training School for Nurses graduated the following young women on May 25th:

Ruby Nellie Furlong, Lillian Victoria Sherman, Stella Kathleen Kenny, Agnes Eleanor Reany, Jessie A. Twillman, Beatrice Pritchard, Nellie Esther Evans, Margaret Culbert, Lillian Esther Hankins, Martha St. John Eakins, Mabel M. Gaskin, Florence Mary Patton, Mabel Dayton, Harriet A. Chism, Lulu Pearl Rogers, Mrs. Margaret D. Hamilton, and Mrs. Lillian MacLernon Carlos.

Manhattan State Hospital, East.—An interesting programme of sports was carried out by the inmates and employees of this institution on Decoration Day, under the refereeship of Dr. J. T. W. Rowe, as follows: Baseball; lawn bowls; 100 yards dash; potato race; crab race; tug of war; 120 yards hurdle race; sack race; egg race; wheelbarrow race; tug of war, women; three legged race; 100 yards dash, page boys; 75 yards dash, women; tug of war, employees. An excellent programme of music was furnished by the hospital band.

Personal.—Dr. Samuel W. Bandler has been appointed adjunct professor of gynecology in the Postgraduate Medical School.

Dr. Doty has been appointed by Health Commissioner Darlington to direct the work of attempting to exterminate the mosquitoes of Staten Island, for which a preliminary appropriation of \$1,000 has been made.

His ambulance struck by a Fulton Street car, Dr. Moody, of the Cumberland Street Hospital, Brooklyn, was thrown to the street and sustained serious cuts and bruises at Pearl and Fulton Streets on May 29th. He was removed to the hospital on a car and was attended by his fellow physicians.

Society of the Medical Inspectors of the City of New York.—A stated meeting will be held Tuesday, June 6, 1905, at the Chemists' Club, 108 West Fifty-fifth Street, at 8.30 p. m. sharp. Order: Executive session; papers of the evening: The Prevention and Management of Summer Diarrhoea Among Tenement Children, by Dr. Charles G. Kerley; The Summer Diarrhoea of Infancy and the Agencies in New York for Its Prevention and Treatment, by Dr. Rowland G. Freeman; Some Remarks on the Practical Working of the Summer Corps, by Dr. Francis J. Murray. Discussion. Dr. A. C. McGuire, president; Dr. Edward M. Thompson, secretary, 315 West Fifty-eighth Street.

The Dinner to Dr. Emmet.—Dr. Thomas Addis Emmet was honored on his seventy-seventh birthday on May 29th at a dinner given at Delmonico's by his medical friends. About 125 guests were present. Dr. Emmet was escorted to the dinner by Archbishop Farley, who pronounced a blessing and also made a brief speech. Dr. E. C. Dudley, of Chicago, made the address of introduction. Others who spoke were Dr. W. M. Polk, Dr. W.

H. Baker, of Boston; Dr. S. C. Gordon, of Portland, Me.; Dr. George T. Harrison, and Dr. F. J. Quinlan. In his remarks Archbishop Farley said: "I never felt more of a layman than I do at this dinner given to the eminent physician, Dr. Emmet. Honor is due to him who stands at the head of the medical profession. What he has achieved in literature, medicine, and surgery is more than sufficient for any one man. He has lifted up for himself a monument for work that will stand long when he is in his grave."

Projects of the Harvey Society.—A new society called the Harvey Society, consisting of laboratory workers in New York city, has recently been established under the patronage of the New York Academy of Medicine. Its purpose is the diffusion of scientific knowledge in selected chapters of anatomy, physiology, bacteriology, pathology, pharmacology, and physiological and pathological chemistry by the means of public lectures by men who are workers in the subjects to be presented. Each lecture is intended to represent the state of modern knowledge concerning the topic treated, and at the same time will be adapted for presentation before an audience, consisting of that portion of the general medical profession who are interested in scientific medicine. It is hoped that through these lectures the common interests of research workers and the medical profession may be profitably cultivated. The fulfillment of the purposes of the society has been entrusted to the hands of the following committee: Dr. Graham Lusk, president; Dr. Simon Flexner, vice-president; Dr. George B. Wallace, secretary; Dr. Frederic S. Lee, treasurer; Dr. Christian A. Herter, Dr. S. J. Meltzer, and Dr. E. K. Dunham. The members of the society consist of two classes, active and associate members. Active members are laboratory workers in the medical sciences residing in New York. Associate members are such persons as may be in sympathy with the objects of the society and reside in New York. The first course of lectures will be given on Saturday evenings during the winter of the year 1905 and 1906 at the Academy of Medicine.

PHILADELPHIA.

The House of Cards, a book issued anonymously, has been attributed by a professor of English in one of the large universities to Dr. S. Weir Mitchell.

Personal.—Dr. Edith Warner Cadwallader has resigned from the chair of Obstetrics in the Woman's Medical College of Pennsylvania, the resignation to take effect upon the election of a successor.

Charitable Bequests.—The Presbyterian Home for Indigent Widows receives \$3,000 and the Philadelphia Orphan Asylum receives \$1,000 from the estate of Rachel Wetherill, which was adjudicated on May 24th.

By the will of Herman B. Blumenthal \$2,000 is bequeathed to the Federation of Jewish charities.

Amusements for Charitable Objects.—Amateur theatricals for the benefit of the Vacation

House for Young Women at Green Tree, Pa., were given at the New Century Drawing Room on May 22nd. The production was under the management of Miss Eleanor S. F. Pue and Mr. Lawrence B. Eyre.

New Buildings for the Methodist Hospital.—On May 23rd four new buildings were formally added to the equipment of the Methodist Episcopal Hospital, of Philadelphia. The buildings are the Mary T. Hunter Memorial Home for Nurses, the Mary Burton Dispensary, a new ambulance stable, and a power house. The buildings cost about \$120,000.

The Kensington Hospital for Women Nurses Graduate.—On Tuesday, May 9th, the following nurses graduated from the Training School for Nurses of the Kensington Hospital for Women:

Miss Anna E. Bennett, Miss Susan S. Cook, Mrs. Grace M. Porter, Miss Willetta C. Bayliss, Miss Mary E. Ross, Miss Kathleen M. Mills, Miss Charlotte E. Matthews, Miss Barbara E. Diamond, and Miss Beatrice E. Boeshore. The Honorable G. Harry Davis and Dr. Charles P. Noble delivered addresses.

Chester County Hospital Nurses.—The annual commencement exercises of the Training School for Nurses of the Chester County Hospital were held in the chapel of the West Chester State Normal School on May 26th. The following young women received the diploma of trained nurse:

Miss Agnes McFarland, of Centre Square, Montgomery County; Miss Dorothy Paschall, of Newfield, N. J.; Miss Martha B. Pierce, of Upland, Delaware County; Miss Alice A. Weed, of West Chester.

Scientific Society Meetings for the Week Ending June 10, 1905.—Monday, June 5th, Philadelphia Academy of Surgery; Biological and Microscopical Section, Academy of Natural Sciences. Wednesday, June 7th, College of Physicians; Association of Clinical Assistants of Wills Hospital. Thursday, June 8th, North Branch, Philadelphia County Medical Society; Pathological Society. Friday, June 9th, Northern Medical Association; West Philadelphia Medical Association.

A Pure Food Decision.—On May 24th, the Supreme Court of Pennsylvania declared that portion of the act of June 26, 1895, commonly known as the pure food law, which provides against the adulteration of drinks when described as foods to be unconstitutional. The opinion was handed down in the case of Kebort, of Crawford County, who was convicted of selling adulterated blackberry wine. This is the same rock on which the national pure food bill was wrecked; but it seems that alcohol must become mixed with pure food laws as well as with politics.

Jewish Maternity Hospital.—At a meeting of the newly elected board of directors of the Jewish Maternity Association a committee of seven was appointed, with David T. Berlisheimer as chairman, to prepare plans for the adding to the hospital of the nursery annex suggested by the president, Mrs. S. Belle Cohn, in her annual report last week. Milton C. Stein was elected assistant secretary, and David Werner Amram, solicitor. The following were elected to the medical staff:

Medical director—Dr. Isaac Leopold. Consulting obstetricians—Dr. Lucy N. Tappan, Dr. Joseph Price. Consulting surgeons—Dr. Lewis W. Steinbach, Dr. Charles P. Noble. Consulting ophthalmologist—Dr. Isaac Leopold. Consulting neurologist—Dr. Francis X. Dercum. Consulting pathologist—Dr. David Riesman. Consulting dermatologist—Dr. J. F. Schamberg. Consulting paediatrician—Dr. Eleanor C. Jones. Obstetricians and gynecologists—Dr. Clara T. Dercum, Dr. Daniel Longaker, Dr. Helen Kirschbaum, Dr. Edwin A. Heller, Dr. Ludwig Loeb, Dr. Leo H. Bernd. Paediatrician—Dr. L. Valentine Levi. Dispensary physicians—Dr. Clara T. Dercum, Dr. Daniel Longaker, Dr. Helen Kirschbaum, Dr. Edwin A. Heller, Dr. Ludwig Loeb, Dr. Leo H. Bernd, Dr. Moses Behrend, Dr. I. Valentine Levi, Dr. Justin G. Schwerin, Dr. Ellis E. W. Given, Dr. D. A. Feldstein, Dr. Louis P. Steinhart. Resident physician—Dr. Elizabeth F. Lewis. Head nurse and superintendent—Mrs. Blanche F. Schloss. Instructor in massage and Swedish movement to the Nurses' Training School—Mr. Louis D. Sinkler.

The Health of the City.—During the week ending May 20, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Malarial fever.....	2	0
Typhoid fever.....	103	16
Scarlet fever.....	34	0
Chickenpox.....	50	0
Diphtheria.....	56	3
Cerebrospinal meningitis.....	3	1
Measles.....	75	1
Whooping cough.....	14	2
Tuberculosis of the lungs.....	40	71
Pneumonia.....	37	37
Erysipelas.....	9	0
Tetanus.....	1	1

The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 14; puerperal fever, 1; diarrhoea and enteritis, under two years, 22. The total mortality was 456, in an estimated population of 1,438,318, corresponding to an annual death rate of 16.49 per 1,000 population. The total infant mortality was 79; 65 under one year and 14 between one and two years. There were 45 still births; 26 males and 19 females. There were thunderstorms on the 14th and 16th. The maximum temperature was recorded on the 15th, when the official thermometer recorded 83°. The humidity was high and the precipitation amounted to 0.96 inch.

Friends' Hospital for the Insane.—The eighty-eighth annual report of the Friends' Asylum for the Insane has just been received. During the year 269 patients were treated; 95 men and 174 women. Of these 29 were discharged recovered, 19 much improved, 24 improved, 19 unimproved, and 16 died. The training school for nurses, in which are both men and women pupils, completed its tenth year. Negotiations are being entered upon to affiliate the asylum school, which is under the charge of Dr. Grace E. White, with that of a general hospital, so that the pupil nurses of each school may have an opportunity to supplement their course by whatever part they may desire in the other schools. The class that graduated in 1904 numbered 13. The superintendent, in his report, puts himself on record as a believer in a training school as a factor in bringing about a higher moral and intellectual standard in the nursing staff, and an increased scientific value of the reports written by trained nurses. The pathological laboratory, under the direction of Dr. Seymour D. Ludlum, has become an indispensable

adjunct to the medical service of the hospital. The medical staff has been studying the possible relationship of neurofibrillar changes to insanity and during the year Dr. Ludlum published the conclusions thus far reached. During the year two advanced students from the Graduate School of the University of Pennsylvania have studied the special forms of morbid mentation under the direction of the professor of psychology. During the year the William Thomas Free Bed was founded by a legacy of \$5,000 under the will of Mary E. T. Lord. Under the will of Hiram Brooke \$5,000 bequeathed to the institution was used for the foundation of the Hiram Brooke Free Bed. Under the wills of Sarah Marshall and Mary Marshall Johnson \$8,669.50 was received by the corporation.

Medicochirurgical College Commencement.—The annual commencement exercises of the Medicochirurgical College were held in the Academy of Music on Saturday, May 27th, at noon. The following candidates received the diploma of doctor of medicine:

Calvin Hayes Elliott, M. Sc. of California; Irwin Lewis Chipman, of Delaware; Robert Warner Howard, of Florida; Samuel Hawkins Martin, of Kentucky; William James Churchill, Roland Stephen Newton, Herbert Mashell Goddard, of Massachusetts; James McFayden, Jr., of Maine; Arthur Harley Coward, Frederick Snyder Hammond, Walter Franklin Keating, George Beale Knight, Benjamin Franklin Ogden, Edward Wood Russell, Clarence Johnson Slack, Maurice Stayer, of New Jersey; Harry B. Fralic, of New York; James Leak Wyatt, of North Carolina; Dr. James E. Mulligan, Dr. William Henry Perry, of Ohio; Roy Cowles McDaniel, of Oregon; Samuel A. B. Barbash, Charles Howard Bee, Albert Roy Bickstein, Albert Monroe Cochran, John Joseph Dailey, John Edward Dailey, William John Davidson, Joseph Rasbold Delavan, George Hursh Ensinger, Jocelyn Joseph Emmens, Alexander Rae Evans, Curtis Clyde Eves, Joseph Bernard Feeley, John Montgomery Gelwix, Abraham D. Halperin, Harry Joseph Herzstein, Frank Tomlinson Hogeland, David Edgar Hutchinson, Jacob Karl Jaffe, Joseph Clement Jenkins, Frank Raymond Keating, Harvey Evert Kendig, James J. Kennedy, John Benjamin Lark, Hugh James Lenahan, John J. Lynch, Howard Wilson Levensgood, Joseph Jacob Levy, Amos Jones Mander, Thomas P. Martin, Mahlon Granville Miller, George U. Grant Mills, Albert Mehrer Moore, John Joseph Moore, James Aloysius McCracken, Arthur McGinnis, Arthur Ray McNeil, Reid Nebinger, Gilbert M. Neubinger, Martin Landis Nissley, Milton Frase Percival, William A. Raiman, Thomas C. Ross, Leo J. Rostow, Jules Maurice Rosenbloom, Lewis Cress Rowles, Burton C. Rumbel, Harry Wieder Salus, Samuel A. Savitz, Joseph Francis Schlatterer, William Kriebel Seibert, Frank Landis Shenk, Floyd A. Shimer, A. Burton Smith, John Leo Smart, Dr. Thomas Butler Snyder, Herbert Alonzo Spencer, Harry Ambrose Stutzman, Eugene Swayne, Nelson Shelly Weinberger, Walter John Whitehouse, Jr., of Pennsylvania; Charles Alfred Davlin, of Wisconsin; Arthur R. Dray, of England; Ardashes H. Merdingan, of Asia Minor; Professor Judson Daland, Emerson Haines Bainbridge, John J. Gilbride, Guthrie McConnell, Frank White, special.

The gold medal for the highest general average in the senior class of the medical department was awarded to Frederick Snyder Hammond, with honorable mention of Jocelyn J. Emmens and James McFayden, Jr. The gold medal for the highest average in the junior class was awarded to Charles C. Manges; in the sophomore class to Frederick C. Dunlop; in the freshman class to Paul G. Weston. On the evening of May 26th the faculty and trustees of the college gave a re-

ception in the clover room of the Bellevue-Stratford Hotel, and addresses were delivered by President Henry F. Walton, Speaker of the State House of Representatives; Professor John V. Shoemaker, Professor Ernest Laplace, Professor Judson Daland, Professor L. Webster Fox, Professor W. Easterly Ashton, Dr. A. C. Buckley, and Edward J. Houston. The commencement oration was delivered by the Honorable William N. Ashman, LL. D.

GENERAL

The Twentieth Century Women's Medical Club, of Cleveland, has elected Dr. Grace E. Cross, president; Dr. Edith Varney and Dr. Amelia Burroughs, vice-presidents; and Dr. Caroline Y. Wentworth, secretary.

The Suffolk County, N. Y., Medical Society elected the following officers on May 4th at its meeting at Riverhead: President, Dr. W. H. Ross, of Brentwood; vice-president, Dr. C. C. Miles, of Greenport; secretary, Dr. Frank Overton, of Patchogue; librarian, Dr. J. H. Benjamin, of Riverhead.

The Westchester County Medical Society elected the following officers on May 18th: President, Dr. T. F. Goodwin; vice-president, Dr. Frank E. Russell; secretary, Dr. C. P. Byington; treasurer, Dr. S. O. Myers; curator, Dr. W. F. Curtis, of White Plains; censors, Dr. H. E. Schmid, Dr. W. S. Fleming, and Dr. A. M. Campbell.

New Hampshire Medical Society.—At the closing session of the New Hampshire Medical Society held in Concord, officers were elected as follows: President, Dr. Ferdinand A. Stillings, of Concord; vice-president, Dr. Ira J. Prouty, of Keene; treasurer, Dr. D. M. Currier, of Newport; secretary, Dr. Granville P. Conn, of Concord; assistant secretary, Dr. Loren A. Sanders, of Concord.

The State Board of Medical Examiners of North Carolina.—On May 17th the State Board of Medical Examiners for North Carolina convened at Greensboro. There were 129 applicants for license, and the board was in session four days. Of the applicants, 88 were successful, 40 failed to make the requisite eighty per cent., and one withdrew. Among the successful applicants was Dr. H. A. Eberle, late of the American army in the Philippines, and now of Greensboro, N. C.

The Milwaukee Medical College graduated the following on May 15th:

A. C. Borchardt, J. E. Bingham, V. Baird, L. Dorpat, C. C. Dettman, J. L. Daniels, E. S. Elliott, L. J. Friend, J. J. France, F. R. Farrell, F. L. Griswold, J. J. Gramling, J. L. Hutchison, J. S. Hansbury, R. E. Hays, F. A. Jackson, F. L. Kelley, J. M. Kelley, N. H. Lewis, W. C. Lohr, J. J. Lunz, B. J. Manhoff, D. C. Miller, R. D. C. Moray, C. L. R. MacCullum, V. V. Nelson (class president), H. F. Pruessing, J. F. Quin, P. H. Rupp, A. J. Somers, J. F. Stein, Max Schnupp, L. N. Schmetz, W. J. Scollard, E. A. Titel, R. A. Vorpahl, and J. F. Zivniska.

Keokuk, Ia., Medical College.—The following graduated from this college on April 25th:

John L. Aleshire, Chester Brigham, Peder J. Bursheim, John A. Cousins, Walter T. Christenson, Earl Cooper, Leonard E. Frazer, Frank W. Fennell, Leo O. Forney, Henry A. Foster, George H. Gray, Leonard Goshorn, Davis W.

Humphrey, Otto E. Harmon, Freeman Haase, James Hinchliff, Joseph W. Hudak, Florence A. Howard, Otto E. Haisch, Oliver P. Jamison, Jens V. Jorgenson, Clarence J. Kepler, Harry V. Kitzmiller, Alfred L. Lafferty, Verner T. Lindsay, Oliver W. McGrew, Wilson F. McBill, William E. McClain, Arthur S. Monzingo, William L. Munn, Fred H. Miller, Charles V. Moorhouse, Jesse C. Moore, Henry J. Mullin, Edward E. Morgan, Earl H. Noble, Lemuel P. Peters, H. William Plummer, Roscoe Pollock, Sherman Ripperton, James C. Russell, Fred W. Rolfs, Fred T. Rucker, Thomas A. Sinclair, William W. Stelen, Homer Stronsinger, Edwin F. Stannus, Clyde S. Smith, Alexander C. Whitehill, Earl A. Warner, and Ernest A. Wilkinson.

Louisiana State Medical Association.—The following officers of this association were elected at the last annual meeting: President, Dr. C. J. Ducote, of Avoyelles Parish; first vice-president, Dr. J. T. Oechsner, of Orleans Parish; second vice-president, Dr. J. J. Ayo, of Lafourche Parish; third vice-president, Dr. D. R. Sartor, of Richland Parish; counselor, second congressional district, Dr. E. J. Granger, of Orleans; counselor, third congressional district, Dr. H. L. Ducrocq, of Lafourche; counselor, fourth congressional district, Dr. N. K. Vance, of Caddo; counselor, fifth congressional district, Dr. R. F. Harrell, of Lincoln; counselor, sixth congressional district, Dr. C. M. Sitman, of St. Helena; counselor, seventh congressional district, Dr. C. A. Gardiner, of St. Landry; nominees for the State Board of Medical Examiners, Dr. E. L. McGehee and Dr. M. J. Magruder. The next meeting place will be New Orleans, on the second Tuesday in May, 1906.

Poisonous Foods and the Washington Legislature.—The legislature of Washington State, in view of the fatalities consequent upon recent mistakes by children and others, has passed the following act: In relation to poisons and prohibiting the combination of poisonous substances with crackers, bread, or other preparations in any manner resembling or in similitude of any edible product and prescribing penalties for its violations;

Be it enacted by the legislature of the State of Washington:

Section 1. It shall be unlawful for any person to sell, offer for sale, use, distribute, or leave in any place, any crackers, biscuit, bread, or any other preparation resembling or in similitude of any edible product, containing arsenic, strychnine, or any other poison.

Sec. 2. Any person violating the provisions of this act shall upon conviction be punished by a fine of not less than fifty dollars nor more than five hundred dollars.

It appears that children have eaten a biscuit or cracker intended for rats only and loaded with poison for the sole purpose of exterminating the vermin.

Memphis Hospital Medical School.—The commencement exercises of the Memphis Hospital Medical College were held at the college building on April 28th. The list of graduates is as follows:

J. C. Ayres, of Tennessee; J. S. Abney, of Alabama; Rupert Butler, of Arkansas; E. J. Banks, of Mississippi; S. H. Barron, of Mississippi; W. W. Beach, of Indian Territory; J. C. Burdett, of Louisiana; Thad. Cothern, of Arkansas; J. Hugh Carter, of Tennessee; R. W. Carter, of Arkansas; W. T. Collum, of Mississippi; A. R. Carter,

of Louisiana; W. W. Carter, of Texas; J. L. Cox, of Indian Territory; S. S. Caruthers, of Mississippi; C. E. Duve, of Texas; J. C. Denman, of Mississippi; C. T. DeLoach, of Louisiana; S. E. Eason, of Mississippi; Harvey Embree, of Texas; H. E. Griffin, of Mississippi; C. W. Garrison, of Texas; F. A. Gray, of Arkansas; Robert L. Hill, of Alabama; J. F. Haynie, of Mississippi; R. J. Jones, of Mississippi; J. A. Joyner, of Louisiana; M. B. Key, of Mississippi; Ellis Lamb, of Arkansas; J. B. Lightfoot, of Arkansas; H. M. Lyda, of Alabama; Charles McCallum, of Texas; J. Harvey McNeill, of Mississippi; J. A. McCoy, of Mississippi; B. F. McArthur, of Mississippi; J. T. Mills, of Oklahoma; Frank Nisbett, of Arkansas; A. J. Newman, of Louisiana; John Pugh, of Louisiana; T. A. Russell, of Texas; A. W. Rhyne, of Mississippi; F. E. Rushing, of Texas; H. P. Simpson, of Mississippi; D. K. Sauls, of Tennessee; C. E. Shackelford, of Tennessee; J. A. Vance, of Mississippi; W. E. Webster, of Arkansas; W. E. Williamson, of Tennessee; R. F. Wheat, of Mississippi; J. L. Wright, of Texas.

Maryland Medical College.—The following graduated from this college on May 5th:

William Walter Abbott, Ira A. B. Allen, William Gadson Allen, Lawrence A. Baker, Clem Campbell Ballard, Blaine Berthold Barton, Oscar Burnham Beer, A. Marvin Bell, John Henry Bird, James W. Bishop, Lester B. Bradford, Henry Gwyn Branham, Sidney J. Burleson, Edward B. Claxton, Lafayette Coffman, Francis Oliver Darby, Virgil Lee Darby, Walter G. Dempsey, Jill J. Devoti, Charles L. Dichter, Ezra A. Dickey, John Melvin Fadeley, Willis Henry Faulkner, Chester Arthur Flegler, Clark Stevenson Fortney, Gilbert David Furbee, John Head Gayle, Leslie Handlin George, Harry Homer Gessler, Martin Van Buren Godbee, Edwin B. Goodall, Lycurgus Martin Gurley, U. Philo Hackney, Walter M. Hammett, Charley I. Hammond, Cecil de J. Harbord, John Hampton Hare, B. Woodward Hazell, William F. Hoeler, Oliver C. Holley, John Oscar Hunter, James R. Hunter, William D. Jones, William Eli Kay, John J. Kerr, Henry Albert Kiles, Joseph U. Kimble, Theodore W. Koldeaway, Walter Eyan Lee, George A. Leonard, John C. McCoy, Henry McMillan, James M. Meason, Clarence H. Mercer, E. Frederic Morris, Carlisle Nottingham, Benjamin A. Owen, Rollin B. Page, J. W. Payne, Newton I. Parr, Harvey Hinchman Pettry, Charles Lee Porch, Benjamin W. Peck, F. W. C. Quinn, James B. Rankin, Cirilo L. Rodriguez, Francis D. Roelkey, Charles C. Rumsisell, William J. Rysanek, J. W. Schlieder, M. Edward Seale, J. Benjamin Shannon, H. William Shaw, Walter F. Shepherd, George W. Sisler, Opie W. Swope, J. R. Sudler, J. T. Sullivan, Joseph D. Talkin, Edward H. Thompson, William P. Thompson, Neill A. Thompson, Lewis B. Thomson, Mosely J. Toney, Seneca S. Turner, Walter Alva Weed, John H. Weil, Okey N. Windle, Arch A. Wingrove, Albert T. Young, W. K. Zimmerman.

University of Maryland.—The following graduates of the medical department of the University of Maryland, eighty-three in number, were announced on May 9th:

Samuel Luther Bare, Robert Parke Bay, Chandos M. Benner, James Snow Billingslea, Ira Burns, Sydenham Rush Clarke, Frederick De Sales Chappelier, John Martin Elderchide, George William Mahle, James G. Matthews, Harry Downman McCarty, W. Arlett Parvis, John William Pierson, Daniel E. Rensberg, Albert Leigh Sanders, J. Holmes Smith, Jr., William Henry Fisher, Leo J. Goldbach, Brooke I. Jamison, Jr., Henry C. Houck, Francis White Janney, Eugene Kerr, Herbert L. Kneisley, William A. Knell, Roscoe Conkling Metzel, Robert Levis Mitchell, J. Albert Nice, Samuel T. R. Revell, John L. Riley, Anton G. Rytna, W. Henry Smithson, Jr., and William E. Elliott Tyson, of Maryland; Julian Warrington Ashby, Alvah Parish Bohannon, Edward V. Copeland, George Blight Harrison, Harry Equilla Jenkins, and Oscar S. Owens, of Virginia; Frank Burden, Samuel William Hammond, and Edgar Brown Lafave, of West Virginia; Elmer Hall Adkins, Baird U. Brooks, Arthur Bascom Croom, Alpheus Wood Disosway, Edwin Ferreebe Fenner, Oswald Ottmar Kafer, James P. Matheson, James Albert Stone, John Shaw Gibson, Milton R. Gibson, Archibald Wright Graham, Henry Hiram Hodgkin, Hamner C. Irwin, John W. Parker, Jr., and Willard James Riddick, of North Carolina; Vance W.

Brabham, Edward McQueen Salley, and Steuart Baskin Sherard, of South Carolina; George Skinner McCarty and William Benjamin Warthen, of Georgia; John Edgar Rooks, of Tennessee; Frederick J. Waas, of Florida; Roscoe C. Carnal, David A. DeVanny, William Morris Mitchell, William W. Halla, Harold Edson Minor, and William Wordsworth Riha, of New York; Charles Gallery Croushore, James Eugene Dwyer, Harry Moore Felton, John P. McGuire, and William Cuthbert McGuire, of Pennsylvania; Benjamin Franklin Tefft, Jr., and Seth DeBlois, of Rhode Island; Oliver Justin Ellis, of Vermont; Julius Levin, of Connecticut; John Joseph Carroll, of Massachusetts; Edward Lawrence Casey, of New Hampshire; Manuel Duemo, of Porto Rico; Nagib Kenawy, of Egypt; Kalil Magid Koury, of Syria.

University College of Medicine, Richmond, Va.—This institution graduated the following in medicine on May 18th:

Fielding Lewis Ashton, of Hooes, Va.; Coleman D. Bennett, of Keeling, Va.; Richard Alfred Bennett, Jr., of Toshes, Va.; John Otto Boyd, of Winchester, Va.; John Garnett Broadbuss, of Bowling Green, Va.; Joseph Haskell Chiles, of Fort White, Fla.; Joseph Dorsey, of Piedmont, W. Va.; E. Hale Connelly, of Walthall Store, Va.; George Marion Cooper, of Clinton, N. C.; James Harvey Craft, of Bramwell, W. Va.; Harry M. Crowe, of Berryville, Va.; John Williamson Daugherty, Jr., of Richmond, Va.; William Dalton Deshazo, of Spencer, Va.; Ernest Egbert Epperson, of Naruna, Va.; Robert Scott Fitzgerald, of Richmond, Va.; Rawley H. Fuller, of Danville, Va.; Alfred Ludwell Hammer, of Elkton, Va.; Delos D. Hooper, of Tuckasee, N. C.; Frank Ernest Irons, of Pickaway, W. Va.; James Warren Knepp, of Roanoke, Va.; Wiley Wilson Kootz, of Broadway, Va.; Jefferson Franklin Landen, of Chingapin, N. C.; George Price McCoy, of Franklin, W. Va.; Samuel Austin McFerrin, of Friar's Hill, W. Va.; Richard H. Manson, of Warfield, Va.; Moir S. Martin, of Stuart, Va.; D. C. Mayers, of Stony Creek, Va.; Henry Taylor Miller, of Washington, Va.; Ben James Montgomery, of La Crosse, Va.; Clarence V. Montgomery, of La Crosse, Va.; Schuyler Barclay Moon, of Richmond, Va.; E. Ackley Moore, of Castleman's Ferry, Va.; Heber P. Newman, of Fort White, Fla.; Cullen S. Pitt, of Barton Heights, Va.; Oscar Lee Ramsey, of Sandy Level, Va.; William Sterling Robertson, of Richmond, Va.; Robert Douglas Roller, of Charleston, W. Va.; Clyde Fenton Ross, of the Trappe, Va.; Joseph Hubbard Saunders, of Washington, N. C.; Fred L. Smith, of Lawton, W. Va.; Shelton Stringer, of Brookville, Fla.; George Fugett Turman, of Willis, Va.; William L. Watts, of Monitor, Va.; William Lee Weadon, of Bluemont, Va.; Robert Camden Whitehead, of Lynchburg, Va.; Roy Folsom Williams, of Sowers, Va.; William Franklin Williamson, of Alexandria, Va.; Wade Hampton Young, of Zackville, W. Va. Department of Dentistry.—Degree of Doctor of Dental Surgery: L. Cabell Bell, of Waterbury, Conn.; Benjamin Bloxton, of Richmond, Va.; Carl C. Bowman, of Pratts, Va.; R. Owen Canada, of Danville, Va.; Frank Garland Chamblee, of Wakefield, N. C.; John Mabrey Coleman, of South Boston, Va.; William Claude Fitzgerald, of Chatham, Va.; Burnam Oscar Grove, of Luray, Va.; Chancy Highsmith, of Parkersburg, N. C.; Richard Jones, of Virginia Beach, Va.; Maryan Buford Lewis, of Culpeper, Va.; David K. Lockhart, of Asheboro, N. C.; Frank Bell Miller, of Newport, Va.; James Oscar Quaintance, of Boston, Va.; R. Floyd Waller, of Leda, Va.; Lawson Carter Womack, of Whittle's Depot, Va.; J. Smith Yates, of Grifffinsburg, Va.; Paul Preston Yates, of Morrisville, N. C.

American Medical Association.—The forthcoming session of the American Medical Association promises to be most interesting and well attended, not only from a scientific and social point of view, but for the many liberal inducements and stop over privileges which are offered by the various railroads throughout the country. Of a number of special trains, the Overland Limited will leave Chicago via the Northwestern line Thursday, July 6th, at 8.02 p. m., going through Salt Lake City and Ogden and arriving at Portland,

Monday afternoon, July 10th, at 5.25. This will permit a stop over (if desired) of one day at the quaint, beautiful, and historic city of Salt Lake, and there will be no increase in railroad fare for this trip, which will enable one to return after the session is over, via any other of the United States lines of railroad or via the Transcontinental Canadian Pacific Railroad. Going via the Northwestern Line from Chicago affords a daylight ride through the wonderful Rocky Mountain scenery of the western States, and for some 200 miles of Columbia River scenery. The fare is \$56.50 for the round trip from Chicago; tickets valid ninety days from date of sale.

The White Pass and Yukon Route is offering inducements under most favorable auspices to those who desire to visit Skaguay, Dawson, and other Alaska points.

The Canadian Pacific Railway offers a delightfully picturesque trip through the Canadian Rockies with stop over privileges, the fare for the round trip from Chicago being also \$56.50.

For full details of all the above itineraries, Dr. Liston H. Montgomery, 92 State Street, Chicago, Ill., will gladly furnish the desired information.

Hospital Appointments.—The following members of the graduating class of 1905 of the Medicochirurgical College, of Philadelphia, have received hospital appointments as follows:

Medicochirurgical Hospital, Dr. W. F. Keating, Dr. J. J. Moore, Dr. C. H. Elliott, Dr. S. H. Martin, Dr. H. B. Fraile, Dr. R. Nebinger, Dr. B. Swayne, Alternates, Dr. G. M. Neuburger, Dr. A. McGinnis, Dr. J. R. Delavan, Dr. F. R. Keating, Dr. J. P. Kennedy, Dr. M. L. Nissley, Dr. R. C. McDaniel.

Frankford Hospital, Dr. John J. Lynch and Dr. Thomas C. Ross.

Jewish Hospital, Dr. Herbert M. Goddard and Dr. Gilbert M. Neuburger.

Prince of Peace Maternity Hospital, Dr. William J. Churchill.

Samaritan Hospital, Dr. Milton F. Percival and Dr. William A. Raiman.

Allentown Hospital, Allentown, Pa., Dr. Mahlon G. Miller.

Atlantic City Hospital, Atlantic City, N. J., Dr. Samuel Barbash.

St. Vincent's Hospital, Erie, Pa., Dr. Charles A. Davlin.

Mercy Hospital, Pittsburgh, Pa., Dr. Frederick S. Hammond and Dr. James J. McFayden, Jr.

St. Luke's Hospital, South Bethlehem, Pa., Dr. Jocelyn J. Emmens and Dr. Joseph J. Levy. Alternate, Dr. Roland S. Newton.

McKeesport Hospital, McKeesport, Pa., Dr. Joseph B. Feeley.

Lackawanna Hospital, Scranton, Pa., Dr. Thomas P. Martin.

Trenton Emergency Hospital, Trenton, N. J., Dr. Howard Wilson Levenood.

Trenton State Hospital, Trenton, N. J., Dr. Clarence J. Slack.

Westchester Hospital, Westchester, Pa., Dr. D. Edgar Hutchinson.

City Hospital, Wilkesbarre, Pa., Dr. James J. McFayden, Jr., and Dr. A. Burton Smith.

Mercy Hospital, Wilkesbarre, Pa., Dr. Hugh J. Lenahan.

The following are on the eligible list for the Philadelphia General Hospital: Dr. Jocelyn J. Emmens, Dr. Frederick S. Hammond, Dr. Abraham D. Halperin, Dr. Joseph R. Delavan, Dr. James J. McFayden, Jr., and Dr. Samuel Barbash.

Statement of Mortality in Chicago for the Week Ending May 20, 1905, compared with the

preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	May 20, 1905.	May 13, 1905.	May 22, 1904.
Total deaths, all causes.....	530	450	483
Annual death rate per 1,000.....	14.11	11.79	13.04
By sexes—

American Laryngological Association.—At the sessions of the twenty-seventh annual congress of this association, to be held at the Hotel Chelsea, Atlantic City, June 1st, 2nd, and 3rd, members hope to hear the following papers:

President's Address, by Dr. Clarence C. Rice; A Case of Nasal Hydrorhœa, by Dr. D. Bryson Delavan; Partial Turbectomy Followed by Acute Otitis, Mastoiditis, Sigmoid Sinus Thrombosis, with Extension to Internal Jugular Vein, by Dr. Charles H. Knight and Dr. James F. McKernon; Further Report on a Case of Lupus of the Pharynx and Nasopharynx (*Transactions*, 1904, page 123), by Dr. Herbert S. Birkett; The Treatment of Acute Inflammations of the Nasal Accessory Sinuses, by Dr. Thomas Hubbard; An Intranasal Operation for Draining the Frontal Sinus, by Dr. E. Fletcher Ingals; Exhibition of Sections of the Nose of Various Animals, by Dr. John M. Ingersoll; "Symposium" on Sinus Disease: (a) What Symptoms in Diseases of the Nasal Sinuses Demand Radical Surgical Inter-

vention? (b) What Have Been the Comparative Results of Conservative and Radical Methods of Treatment? The Maxillary Sinus, by Dr. Robert C. Myles and Dr. George A. Leland; The Frontal Sinus, by Dr. C. G. Coakley and Dr. William E. Casselberry; The Ethmoidal Sinus, by Dr. John O. Roe and Dr. John W. Farlow; The Sphenoidal Sinus, by Dr. J. W. Gleitsmann and Dr. T. Passmore Berens; general discussion; Deflection of the Nasal Septum in Children, by Dr. Arthur A. Bliss; A Second Note on a Case of Sarcoma of the Nose, by Dr. J. Price-Brown; A Further Study of Hay Fever, Clinically, with the Employment of Pollantin, by Dr. Alexander W. McCoy; Amygdalotomy, the Basis for the Treatment of Tonsillar Affections, by Dr. George B. Hope; Gangrene of the Tonsil, with Report of Cases, by Dr. Charles W. Richardson; Sequel to a Case of Epithelioma of the Larynx, Shown to the Association Two Years Ago (*Transactions*, 1903, page 98), by Dr. Walter F. Chappell; Two Cases of Foreign Body (Impacted) in the Oesophagus, by Dr. Gordon King; Papilloma of the Larynx in Children, by Dr. J. Payson Clark; Rest in the Treatment of Laryngeal and Pulmonary Tuberculosis, by Dr. W. Peyre Porcher; The Relation Between Laryngeal and Pulmonary Tuberculosis, by Dr. Walter F. Chappell; Complete Adhesion of the Vocal Bands Following Tracheotomy After Diphtheria, by Dr. D. Braden Kyle; Rogers's Modification of the O'Dwyer Treatment of Chronic Stenosis of the Larynx, by Dr. D. Bryson Delavan; (a) Papilloma of the Nasopharynx Simulating Epithelioma; (b) Fibroma of the Larynx in a Child of Three Years, Necessitating Tracheotomy; Subsequent Laryngofissure for Removal Followed by Prolonged Intubation, by Dr. Thomas J. Harris; A Case of Laryngeal Diphtheria in an Adult (Necessitating Intubation) Complicating Cerebrospinal Meningitis, by Dr. William K. Simpson; An Unusual Case of Edema of the Glottis, by Dr. Emil Mayer.

Personal.—Regius Professor Osler sailed for England on the *Cedric*, May 19th.

Governor McDonald, of Colorado, on May 11th, appointed Dr. L. E. Lemen, of Denver, a member of the State board of health, to succeed Dr. Hubert Work, of Pueblo, who resigned because of inability to attend the meetings of the board regularly.

Dr. A. T. Grill, of Cleveland, has been appointed house physician at St. Joseph's Hospital and has entered upon his duties. Dr. Grill was for a number of years connected with the Charity Hospital of Cleveland.

Dr. W. L. Whittington, a physician at the insane hospital at St. Joseph, Mo., was elected superintendent of the colony for the feeble minded and epileptics at Marshall on May 13th. Dr. L. M. Thompson, formerly superintendent, resigned at the last meeting of the board. There were many applications for the appointment.

Dr. Thomas Opie, one of the founders of the College of Physicians and Surgeons, of Baltimore, and who for thirty-three years has been dean of the faculty and professor of gynecology, has resigned. Dr. Charles F. Bevan, professor of surgery, has been elected dean of the faculty and has assumed his duties as such.

The Wisconsin College of Physicians and Surgeons has strengthened its faculty and its standing by the acquisition of Professor Victor Hugo Bassett, of Johns Hopkins University, who will be professor of pathology and director of the Marks laboratories of pathology and bacteriology. Dr. Bassett will be the first incumbent not to engage in private practice.

Dr. William H. Taylor's class in medical jurisprudence, 1904-1905, of the Medical College of Virginia, have presented him with a silver loving cup as the result of the attacks made on their in-

structor following his famous lecture on the immortality of the soul.

Dr. John F. Winn, of Richmond, Va., has been elected by its board of trustees, professor of clinical obstetrics in the University College of Medicine of that city. For a number of years Dr. Winn has successfully filled the position of lecturer on obstetrics in the same institution.

Nurses Graduate.—The Good Samaritan Hospital, of St. Louis, Mo., has granted diplomas to:

Mamie Sutter, of St. Louis; Edith Coffey, of Stonington, Ill.; Lucy Engle, of Louisiana, Mo.; Emmeline Padgett, of Okawville, Ill.; Helen Landray, of Newark, N. J.; and Lillian Sharpe, of Eureka Springs, Ark.

The Presbyterian Hospital Training School, of Philadelphia, has graduated the following:

Maude A. Frantz, of Lancaster; Bertha H. Guilfoyle, of Philadelphia; Emma L. Lott, of Bridgeton; Carrie M. Marks, of Littlestown, Pa.; Estelle Pratt, of Cobourg, Ont.; Mabel E. Reazor, of Sayre, Pa.; Carrie Robeson, of Wilmington; Mary Schwer, of Jersey Shore, Pa.; Clara A. Smitheman, of Philadelphia; Alice M. Spang, of Reading; Beatrice M. Tyack, of Hightstown, N. J.

The Philadelphia Lying-in Charity and Nurse School graduates:

Leonore Albert, of Stroudsburg; Ida Bent, of Nova Scotia; Anna Booz, of Holmesburg; Esther Burt, of London, Eng.; Florence Cloud, of Colwyn; Grace Franklin, of Town Hill; Florence Greenwood, of Chester; Amanda Guy, of Yardley; Grace L. Irvine, of St. John, N. B.; Margaret M. Jones, of Phoenixville; Teresa Layou, of Forty Fort; Caroline M. Lee, of Atlantic City; Katherine Lenahan, of Germantown; Clara Lynn, of Yardley; Helen McCarthy and Katherine Neiswander, of Shenandoah; Carrie Rall and Jennie L. Sine, of Williamsport; Anna Thomas, of Moorestown; Elizabeth Waldron, of Utica, N. Y.; Barbara Willis, of Honesdale; Minnie Van Gilder, of Philadelphia.

The following nurses have graduated from the Medico-Chirurgical Hospital, of Philadelphia:

Kathryn L. Herr, Anna Loretto Hart, Adelaide I. Sprenger, Minnie E. Worrest, Flavilla M. Warner, Ida May Kurtz, Mary Augusta Greene, Maude B. Seaman, Clara Louise Ruth, Marjorie D. Clement, Mary Madalen Quinn, Della May Fletcher, Alma F. Getz, Emma R. Camper, Eva Cecil Cunningham, Clara Viola Leonard, Rachel M. Rambo, Alice M. Conard, Margaret E. Leber, and Nellie Lucile Fox. A special diploma was also awarded to Miss Emma G. Van Ness, who has completed a postgraduate course along special lines.

The following have graduated from University Hospital, Baltimore:

Ruth Rozalia Kuhn, Dora Iola Brosenne, Charlotta Lee Schaefer, Leila Griffith Owens, Lila Holmes Trenholm, Millicent Geare, of Maryland; Nellie Rives Ferrell, Letty Terry Jones, Eleanor Virginia Gilder, of Virginia; Nellie Harrison Hilliard, of North Carolina; Elizabeth Richards Bayley, of Pennsylvania; Margaret Brand Cowling, of Massachusetts.

The graduates of the Mayfield Sanitarium Nurses' Training School, St. Louis, are:

Misses Bertha E. Butler, of Evansville, Ind.; M. Ette Kincheloe, of Sidney, Ill.; Nora Homan, of Lamar, Mo.; Pearl I. Elliott, of Gower, Mo.; May Sterl, of Mt. Carmel, Ill.; Marion R. Tyzzer, of St. Louis; Ruth Russell, of Geneva, Neb.; E. H. Osborn, of St. Louis; Maria Louise Nivin, of Bunker Hill, Ill.

Graduation exercises for the training school of nurses of the Niagara Falls Memorial Hospital were held May 8th, and nine young women were given diplomas. They were:

Jean Mingay, Edythe Grace Shape, Helena Morrison, Mabel Stewart, Bella R. Stewart, Lily Knox, Nell Berry, Anna Strayne, and Nellie E. Simons.

PRESSE MEDICALE.

May 3, 1905.

1. Anæsthesia with Atropine, Morphine, and Chloroform (Method of Dastre and Morak). By TH. TUFFIER.
2. The Causes Which Bring About Miscarriage.

By E. BONNAIRE.

1. **Anæsthesia with Atropine, Morphine, and Chloroform.**—Tuffier is very favorably impressed by his experience in the administration subcutaneously of morphine and atropine a few minutes before giving chloroform. He is accustomed to inject one and a half to two centigrammes of morphine with one half milligramme of atropine subcutaneously and fifteen minutes later to proceed with the chloroform. Although only a small quantity of the latter drug is employed complete and profound anæsthesia is quickly obtained with no stage of excitement.

2. **The Causes Which Bring About Miscarriage.**—Bonnaire says that in most cases the actual cause of a miscarriage escapes observation. Commonly it is attributed to a vague traumatism, often to a fall on the stairs. He reduces the pathogeny of abortion to this formula; the ovum plays the part of a foreign body and is expelled. first, when it is itself changed by death, separation, or other cause, though contained in a normal uterus; second, when, whether healthy or not, it is contained in an intolerant uterus. The causes which may produce these conditions are changes in the ovum, pathological conditions in the uterus, faults in the general health of the woman, and vitiation of the spermatozoa. He finds that traumatism varies greatly in its power to interrupt pregnancy according to its intensity, the seat of its application, its severity and repetition, the age of the fœtus, and the degree of the idiosyncratic irritability of the uterus.

May 6, 1905.

1. Cerebrospinal Meningitis Due to Meningococci. Some New Points in Their History. By CHAUFFARD.
2. The Present Epidemic of Cerebrospinal Meningitis in America. By JARVIS.

1. **Cerebrospinal Meningitis.**—Chauffard describes a case which came under his observation. It is not a new disease, but one that can be recognized in the descriptions of certain epidemics of the fifteenth and sixteenth centuries. From the observations of other writers he finds that the meningococci enter the meninges from the nasal fossa by way of the lymphatics, and agreeing with them he advocates treatment by hot baths and lumbar puncture. It is difficult to recognize his new points in the history of meningococci unless they are contained in the quotations from the recent work of Pinto, according to whom he says there is a great resemblance between the gonococcus and the meningococcus as each has the same form, size, diplococcal arrangement, and intracellular position, have the same color reactions,

and are both decolorized by Gram's method. Even their cultures are said to resemble each other and they produce similar toxins; still they can be differentiated.

2. **Epidemic of Cerebrospinal Meningitis in America.**—Jarvis traces the course of the late epidemic in the United States and then gives a short history of previous epidemics, beginning with the disease in 1806. The labors of American bacteriologists and the methods of treatment which have been employed are briefly mentioned.

May 10, 1905.

1. The King's Evil. The Royal Touch for Scrofula in France and England. By LANDOUZY.
2. The Antituberculosis Dispensary of Lyons. By COURMONT.

1. **The King's Evil.**—Landouzy gives an interesting account of the ancient custom of touching to cure scrofula as it was practised in England and France. The common belief was that kings were possessed by Divine grace of the power of curing this disease in this manner, which they did with considerable ceremony, the patients afterward receiving alms. The paper is illustrated by several curious old cuts representing the ceremony as it was performed. In England the custom seems to have originated about the time of Edward the Confessor, and to have finally passed away at the accession of the Georges.

2. **The Antituberculosis Dispensary of Lyons.**—Courmont gives a description of the building and of the work carried on therein. It is a new section of the bacteriological institute of Lyons founded in 1899.

May 13, 1905.

1. The New General Hospital at Calcutta. By JEANSELME.
2. Technics of Palatoplasty. By BROCA.

1. **Hospital at Calcutta.**—Jeanselme gives a description of this hospital with plans of the different floors and of the pavilions for contagious diseases.

2. **Technics of Palatoplasty.**—Broca says truly that this is an operation which demands special skill and experience. The patient is anesthetized and placed on the table, so the head will hang over the edge. The tongue is then drawn out so as to expose the palate with its fissure. The margins of the fissure are freshened by the removal of a strip of mucous membrane. After the bleeding is checked an incision is begun behind the last molar tooth, carried forward, and passed a good centimetre beyond the anterior angle of the fissure. When the cleft is large the incision is prolonged backward between the soft palate and the cheek, so as to obtain a greater mobility. With an ordinary bistoury, guided by the index finger of the left hand, the incision thus marked out is deepened to the bone and the soft parts are then elevated by means of a Trelat's raspator, a manœuvre, the details of which the writer gives

with great care, until they are thoroughly mobilized. Bleeding is then checked by means of pressure with the fingers against the bone. After proper mobilization has been accomplished, the flap on each side is seized with forceps, and the two flaps are brought together and sutured along the median line.

A Fifth Eruptive Disease, Epidemic Megalerythema,

By L. CHEINISSE.

Epidemic Megalerythema.—Cheinisse has collated the literature in regard to a variety of measles which has been described under the various designations of acute infectious erythema, morbilliform infectious erythema, megalerythema epidemicum, erythema simplex marginatum, etc., but has added little if anything to our knowledge regarding the disease.

May 10, 1905.

Mechanical Effects of Hypertension of the Cardioaortic System,

By VAQUEZ.

Hypertension of the Cardioaortic System.—Vaquez speaks first of the accentuation of the second aortic sound and then considers hypertrophy of the left ventricle, dilatation of the aorta, rupture of the heart or of the aorta, dilatation of the heart, aortic insufficiency, and mitral insufficiency, all of which may be the results of hypertension.

LYON MEDICAL.

May 7, 1905..

1. Congenital Stenosis of the Pylorus in an Infant,

By AUDRY and SARVONNAT.

2. Indications for the Surgical Treatment of Biliary Lithiasis,

By COTTE.

1. Congenital Stenosis of the Pylorus in an Infant.—Audry and Sarvonnat report the case of a child, 3 days old, brought to them on account of continual vomiting. The vomiting persisted and the child died four days later. On autopsy the only lesion found was a stenosis of the pylorus. The stomach was not dilated and there was only a little hypertrophy of its walls except in the region of the pylorus. The pylorus was represented by a very hard ring of normal color with a very small orifice. When the stomach was filled with water the liquid filtered through slowly, drop by drop, into the duodenum.

2. Surgical Treatment of Biliary Lithiasis.—

Cotte reviews briefly the indications given by Kehr and the method of operation employed by that surgeon. His advice is to wait in the simple forms of cholecystitis, but to operate as quickly as possible in the purulent and gangrenous forms. Hydrops of the gall bladder does not justify intervention, but empyema of that viscus, as well as pericholecystic suppuration, demands it. Frequent hepatic colic without icterus and without passage of calculi necessitates operation on account of the general health of the patient, while attacks accompanied by icterus and by the passage of calculi should be treated medically. He

advises operation when the morphine habit has resulted from very frequent attacks. Acute occlusion of the duct should be treated medically, but little time should be lost in the medical treatment of chronic occlusion. In cases of chronic icterus of other origin than biliary lithiasis operation is of advantage, as it gives the opportunity to determine whether the biliary retention has been caused by chronic pancreatitis, cancer of the pancreas, or some other condition. Cancer of the gall bladder frequently is caused by lithiasis and an early operation is indicated. Perihepatic and pericholecystic adhesions often cause violent pain which may be relieved by surgical intervention. Such complications as suppurative inflammation of the bile ducts, abscess of the liver, pyloric or duodenal stenosis, obstruction of the intestines by calculi also imperatively demand intervention. It is important to consider the general health of the patient before deciding upon an operation. No operation should be performed on a patient suffering from diabetes, arteriosclerosis, or organic disease of the heart, or other organs, unless it is one of urgency.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE.

March 12, 1905.

1. On Diminution of Resistance to Infections as a Cause of Death in Frogs, After the Extirpation of the Thymus Gland,

By G. A. PARI.

2. A Case of Suture of the Heart, with Recovery,

By ETTORE GIULIANO.

3. Conservative Surgery,

By MARIANO MARADEI.

4. On the Therapeutical Value of the Antibacillary Serum,

By GIUSEPPE RICCI.

1. On the Diminished Resistance to Infection After Thymectomy.—Pari has taken up the work initiated by Abelous and Ballard, who removed the thymus gland in frogs, and who obtained a series of phenomena in these animals which pointed to the activity of toxic substances circulating in their blood. The results obtained by the two French observers just named were contradicted by Ver Eecke, who showed, three years later, that the thymus gland might be removed with impunity in debilitated frogs, but that after the operation these animals exhibited a lowered resistance to infection. Pari repeated these experiments, and found that the majority of the frogs in which the thymus gland had been removed recovered completely. A small number died after an illness characterized by discoloration and ulceration of the skin, gastroenteritis, and changes in the various organs, which exhaled a putrefactive odor even during life. This illness the author found to be due to the presence of a certain bacillus which stained with Ziehl, and was not resistant to acids. These bacilli, injected into other frogs with extirpated thymus, produced a fatal infection. The bacillus resembled that of the gangrenous septicæmia of frogs described by Legrain. As the author had for years operated on frogs, and has never seen a case of gangrenous septicæmia among them, he concludes that the extirpation of the thymus diminishes the resistance of these animals to infection.

2. Suture of the Heart Followed by Recovery.—Giuliano, of Catania, reports a case of stab wound of the heart, in which suture was followed by recovery. The patient was a youth of eighteen years, who had been wounded in the thigh, and in the chest at the third intercostal space in the mammary line. The surgeon saw him half an hour after the accident, and he was then in a state of collapse. On auscultation, a peculiar churning noise was heard, and a wound of the heart was suspected. No time was lost in thinking of a method of operating, and a U shaped incision, open externally, was made through the skin, down to the ribs, the cartilages of the third and fourth being cut at about a centimetre away from the sternum. The flap thus made was held aside by an assistant, and the heart with its pericardial pouch was brought forward with the hand. The pericardial wound was found, and was enlarged by means of straight forceps. A wound was then found in the free margin of the right auricle, which involved the coronary artery. The latter could not be ligated, but sutures of silk were introduced during diastole (as during systole the heart escaped into the chest). The pleural and pericardial regions about the wound were then hastily cleansed, and the wound closed, allowing a drain of gauze to pass down to the pericardial wound. The patient slowly rallied and made an uneventful recovery, except that he developed a pleurisy which made him suffer a great deal, but ultimately to get well. The sutures were removed on the eighth day, while the drain was dispensed with as early as on the second day.

March 19, 1905.

1. On the So Called N Rays, By VITTORIO MARAGLIANO.
2. Contribution to the Study of Arterial Tension in Man in Diseased Conditions, By ARISTIDE TORCHIO.
3. Infectious Jaundice, Acute Yellow Atrophy of the Liver, and Biliary Hypertrophic Cirrhosis,

By GINO ZANARDINI.

1. The So Called N Rays.—Maragliano declares his belief in the existence of the n rays. In France opinions of scientists are now equally divided, some answering this question in the affirmative and others in the negative. In Germany the majority of observers now deny the existence of the n rays, and this is the more remarkable because Blondlot is such an eminent physicist (Blondlot, of Nancy, in March, 1903, discovered the n rays while trying to polarize the x rays. He found that while giving off Röntgen rays the tube also radiates another sort of energy which renders a small electric spark more luminous). Maragliano found that his training in x ray work had given him exceptional acuteness of vision, which enabled him to see the effects of the n rays on Blondlot's phosphorescent screens, although he admits that he could not get all the results which have been claimed by the Nancy school, such as seeing the outlines of the heart, and outlining the course of a nerve. In order to see the effects of the n rays, one must have a sharp vision and a great deal of patience, but they exist, in spite of the denials of many authors. The proof will come when mathematicians will give us a demonstration of the existence of these rays.

March 26, 1905.

1. The Interpretation of Some Systolic Murmurs of the Aorta, By G. CURLO.
2. Addison's Disease and Pediculosis, By UGO BENENATI.
3. Abscess of the Right Kidney, Due to Echinococcus, By GIUSEPPE SPADICCI.
4. New Researches on the Morphology of the Elements of the Blood, By TRILO DI TUNISI.
5. The Surgical Treatment of Bright's Disease, By LUIGI CESARI.
6. A Case of Spontaneous Subluxation of the Crystalline Lens, By PIETRO PORRU.

2. Addison's Disease and the Pigmentation Due to Lice.—Curlo warns against an error of diagnosis between Addison's disease and the pigmentation of the skin produced by pediculosis. Phthiriasis is an ancient disease, spoken of by Aristotle, Celsus, and Galen, but even expert clinicians have at times mistaken the peculiar pigmentation produced by lice for the bronzing of Addison's disease. In the latter the parts of the skin normally richest in pigment are usually attacked first, and show brown plaques, which do not appear usually in pediculosis. The mucosæ may show pigmentation in both maladies. According to Briguet the pediculus not only sucks the blood of its victim, but inoculates him with a special poison contained in its saliva, which produces the blue macules. In fact, this author found experimentally that the insects contain a poisonous substance, and succeeded by inoculating this substance in producing blue macules. It is the central portion of the insect which contains the salivary glands that contains this poison. This origin of the blue macules explains their occurrence in the mucosa of the mouth. A differential point between Addison's disease and the pigmentation due to lice is that the debility accompanying the latter improves with proper care and rest, while in the former it is progressively fatal. History records the death of Herod Antiochus, Philip II, etc., as due to pediculosis, but probably an autopsy would have cleared up the true cause of death which undoubtedly was not due to pediculi. The case of Ferdinand II, whose death is not so far removed from our times, was probably one of pyæmia. Hundreds of lice were removed from the bed of this unfortunate king every two hours. Some authors, however, assert that Ferdinand was suffering from cancer, others that he had been poisoned, and still others that he had syphilis. Very probably the debilitated state of his system favored the enormous fecundity of the lice and favored the spread of infection. It is said (Leuwenthal) that a single louse gives birth to a progeny of 18,000 within two months.

3. Abscess of the Kidney Due to Echinococcus.—Spadicii reports a case of renal abscess in the right kidney in a man, aged 37 years, in which the infection with echinococci was demonstrated. Pus and echinococci were found in the urine during an attack of colic. The swelling occupied the entire right superior quadrant of the abdomen, and the colon could be made out in front of it, owing to the presence of tympany. The patient made a good recovery after transperi-

toneal nephrotomy. The chief difficulty in making a diagnosis in such cases lies in the fact that the disease is so insidious. The patient had been suffering from vague pains and slight fever for a long time.

5. **Surgical Treatment of Nephritis.**—Cesari reviews the history of this subject, and summarizes the various statistics published to date. He concludes that the success thus far obtained is encouraging to those who believe that a surgical operation is necessary in the cure of medical diseases of the kidney. The following is the summary of his statistics: In acute nephritis, Pousson had a mortality of 16.21 per cent.; Patel and Cavaillon, of 21 per cent.; Klink, 75 per cent. of cures and 12 per cent. mortality. In cases of chronic parenchymatous nephritis, Klink had 56 per cent. of cures and 28 per cent. mortality; Edebohls, 33.5 per cent. mortality and 25 per cent. cures. In interstitial nephritis Klink had 68 per cent. cures and 11 per cent. mortality, while Edebohls had 38.7 per cent. mortality and 32.36 per cent. cures. In chronic diffuse nephritis Pousson had a mortality of 20.28 per cent.; Patel and Cavaillon, 15.5 per cent. mortality; Klink, 21 per cent. cures and 29 per cent. mortality; Edebohls, 24 per cent. mortality and 12 per cent. of cures. It should be noted that Edebohls with decapsulation alone had only 9.7 per cent. mortality. Good results were obtained by Israel with nephrotomy in simple and hæmaturic nephralgias. In a large collection of cases Guiteras found 16 per cent. cures and 33 per cent. mortality.

RIFORMA MEDICA.

April 22, 1905.

1. A Case of Chronic Indurative Pancreatitis, with Hour Glass Stomach. Gastroplasty. Recovery,
By FRANCESCO PURPURA.
2. Experimental Studies on Tuberculous Endocarditis,
By BINDO DEVECHI.
3. Contribution to the Treatment of Intestinal Obstruction (*To be continued*).

By FERDINANDO GANGITANO.

1. **Hour Glass Contraction of Stomach, Due to Pancreatitis.**—Purpura reports a case of indurative pancreatitis in a woman, aged 45 years, in whom gastroplasty was performed with excellent results, for an hour glass contraction of the stomach. The patient was very much emaciated, and suffered from pains in the abdomen, eructation of gas after eating, vomiting of a large amount of undigested food, etc. A rounded, smooth tumor could be felt sometimes between the umbilical and right parasternal lines, which gradually vanished towards the left side. This tumor was tympanitic on percussion, like the rest of the stomach. A tumor of the pylorus was believed to be present and, as the patient was getting worse, an operation was decided upon. The condition mentioned in the title was found, and gastroplasty, according to the Heinake-Mikulicz method, was performed. The pancreas was found to have a granular surface and a very dense consistence, and there was no glucose in the urine as occurs in the first stages of pancreatic inflammation. Therefore, the pancreatitis was chronic

and indurative in character. It evidently had produced a perigastritis, and thus a constriction of the stomach.

2. **Experimental Tuberculous Endocarditis.**—DeVecchi, of Martinotti's clinic, experimented upon the mode of origin of tuberculous endocarditis. He injected an emulsion of tubercle bacilli into the marginal vein of the ear of rabbits after he had injured the endocardium of these animals by means of probes passed into the carotids. In other animals, the culture of tubercle bacilli was mixed with finely powdered charcoal. The first series of animals were killed about twenty days after inoculation. The heart in two of these animals showed abundant valvular lesions, while in the third there were no cardiac changes. The lesions in the former animals consisted of partial detachment of the aortic valves, and of a deposit of grayish white tubercles. In five other rabbits, killed from 19 to 22 days after the inoculation of tuberculous cultures, mixed with powdered charcoal, three showed no lesions in the endocardium, while the other two showed well developed tuberculous endocarditis. All of these animals showed advanced lesions in the lungs, spleen, etc. In one rabbit the lesions affected the tricuspid and in another the mitral. This series of experiments confirms the results obtained by Michaelis and Blum, who found that traumatism and tuberculous septicæmia can produce a tuberculous endocarditis. In a second series of experiments the author tried to come more closely to the conditions obtaining in human beings. He inoculated the anterior chambers of the eyes of seven rabbits with a watery emulsion of tubercle bacilli. When the tubercles in the iris were well advanced, he produced a simple aseptic traumatism in the endocardium (by probing the carotid or injecting charcoal into the veins) and killed the animals after a certain number of days. In three rabbits thus treated, which were killed four, seven, and eleven days, respectively, after the traumatism, he found the following conditions: In the first rabbit no lesions were at first found except a swelling of the lymphatic glands, some of which were cheesy. A superficial lesion, due to the sound, was found at the aortic valves. In the second rabbit a miliary tuberculosis of the lung and a tuberculous endocarditis were noted. In the third rabbit the tuberculous process involved the lung, the pleura, and the pericardium, but not the endocardium. The author thinks that many of the cases of experimental tuberculous endocarditis in which no bacilli can be found are in reality simple endocarditides, due to toxic influences, and that the same forms occur in tuberculosis in human beings. This can only be demonstrated, however, by injecting tuberculous toxins into animals predisposed by previous or subsequent traumatism of the endocardium.

ROUSSKY VRATCH.

April 9, 1905.

1. On the Bactericidal Principles of the Fibrin of Human Blood,
By N. O. SCHUMOVA-ZIBER.
2. A Case of Primary Endothelioma of the Pleura,
By S. M. POGGENFOL.

3. Injury of the Lower Laryngeal Nerve.
By P. K. BROSHNIOVSKI.
4. Bimanual Dilatation of the Cervix During Labor,
By S. G. KRASHEVSKI.
5. Epidemiology and Parasitology of Malaria in the Native
Quarter of Tashkent, and in the Province of Tash-
kent, By I. S. NAZAROFF and A. L. SCHWARTZ.

1. Influence of Fibrin on Bacterial Growth.—

Schumova-Ziber reports the results of a large number of experiments undertaken with a view of determining whether the fibrin of human blood possesses bactericidal properties. She inoculated a large variety of resistant and non-resistant germs into fibrin or into media prepared with fibrin, and in all cases obtained negative results. She then tried the influence of extracts of fibrin prepared by allowing it to stand in water for some time. She found that the less resistant germs were very promptly affected by these solutions, while the more resistant ones, such as the typhoid bacillus, etc., required a longer contact with the fibrin extracts. The longer fibrin was allowed to remain in water the greater was the proportion of bactericidal bodies which the filtrate contained. Fibrin extracts, thus prepared, were able to neutralize the virulent properties of a large number of germs, and even to affect the vitality of such germs as the cholera bacillus, the typhoid bacillus, and the diphtheria bacillus.

2. A Case of Primary Endothelioma of the Pleura.—The clinical peculiarities of the case reported by Poggenpol were as follows: A very short duration of the disease, which lasted only two months from the appearance of the first subjective symptoms until the patient's death; the absence of cells derived from the tumor in the hæmorrhagic exudate in the pleura; the absence of enlarged lymphatic glands, and the presence of sharp and persistent neuralgic pains in the brachial plexus.

3. Wound of the Lower Laryngeal Nerve.—In the case reported by Broshniowski, a soldier was stabbed in the neck with a long bladed pen-knife, the end of the knife breaking and remaining in the wound. At the autopsy the end of this knife was found imbedded in the sixth and seventh cervical vertebrae, and penetrating into the spinal cord. When the patient was placed on the operating table, his head had to be turned to the left, and this so pressed on the end of the knife that one of the spinal arteries was severed, and a hæmorrhage into the spinal cord followed. The patient died of asphyxia. He was brought to the hospital two days after the accident with the symptoms of paralysis of the recurrent laryngeal nerve, due to the fact that the nerve had become compressed in the cicatrix.

4. Bimanual Dilatation of the Cervix in Labor.—Krashevski recommends the following method for the bimanual dilatation of the cervix during labor, when the narrow and unyielding neck of the uterus prevents prompt delivery: The index finger of the right hand is passed into the cervix, and is hooked under the upper lip thereof, the patient lying on her back and the operator standing at her right side. Then, if only a little

over one finger can be introduced into the os, the index finger of the left hand is passed along that of the right hand until it reaches the cervix, when it is hooked over the posterior lip, with the palmar surface downward. Then traction is made slowly. It is preferable to do this during the pains, as the manœuvre is painful. After from five to eight such stretchings, each of which should take about a minute and a half, the cervix will begin to yield perceptibly. The process should be continued until the womb admits about four fingers, when the whole hand can usually be introduced, or the forceps applied. In fourteen cases in which the author used this method, he has seen neither hæmorrhage nor tears of the cervix.

April 16, 1905.

1. Acute Infectious Diseases in the Elementary Public Schools of St. Petersburg, and the Methods of Prevention,
By W. G. MATVEVEVA.
2. Folding Cot and Stretcher Combined,
By I. M. FEDOROVITCH-VEDER.
3. Hernia of the Tympanic Cavity, By A. S. DE LENSS.

1. Acute Infectious Diseases in St. Petersburg Schools.—Matveyeva analyzes the reports of the school physicians of St. Petersburg for the past four years. A special staff of physicians numbering 37 men is employed for the sanitary supervision of the schools, each of these men having supervision over from 15 to 17 classes, which he visits not less than twice a week. Large schools containing from 12 to 20 classes are visited daily. There are a number of small public schools containing only one class each. In all, there were 330 schools in St. Petersburg in 1904, in which there were 26,269 pupils. In the school year 1903, 1904, 3,126 children were found to have contagious diseases. The chief function of medical inspection is to remove children from schools as soon as possible when a contagious disease breaks out and to prevent their return before they have fully recovered. Frequent inspections are necessary because parents often send children to school with contagious diseases, trying to conceal the true condition. The sanitary inspectors furnish each school with printed cards bearing the names of the children suffering from contagious diseases in their districts. The periods of isolation after each disease are posted in each school, and the teachers must follow these rules. When an inspector finds a case of contagious disease in a school he at once excludes the child, and if he suspects diphtheria he takes a culture, which is sent to the municipal laboratory. A disinfection is then ordered in the school, and the school is sometimes closed for three days, during which it is thoroughly ventilated. If several cases of the same disease develop in one school, the institution is closed during the number of days corresponding to the period of incubation of this disease. If the inspector so orders, the school is not closed after disinfection, but is carefully watched, visited daily, the children inspected, and the sick pupils visited at home. The other schools which are committed to his care the inspector entrusts in such an exceptional case to an assistant furnished in emergencies by the board of education.

Disinfection in the schools is ordered chiefly in the case of diphtheria and scarlet fever. In other diseases the furniture, floors, etc., are simply washed with a disinfectant solution, the class room is well heated, and thoroughly ventilated. All this is done after the school session, without closing the school. During the past year the children have been furnished with slippers which they wear at school only, in place of their shoes, which they remove with their outer clothing. Thus the dust of the street is not brought into the school and the air of the class room is not contaminated in that manner.

3. **Hernia of the Ear Drum.**—De Lenss thinks that some of the apparent polyps that are met with in chronic otitis media are formed in this way, involving such an increase of pressure from within that there is a protrusion of a portion of the mucous membrane through a perforation in the drum. This was the case in the instance recorded here. After an otitis which produced a perforation in the lower posterior quadrant, the inflammation spread to the antrum, and to a large cell in the mastoid. The increased inflammatory exudate produced a great deal of pressure upon the walls of the middle ear and neighboring cavities, and the mucous membrane, having filled all the available space in the process of swelling, began to protrude through the perforation, thus arresting the discharge from the ear. A mastoid operation was performed, demonstrating that this theory had been correct, and that the supposed polyp had been only a protrusion of a swollen mucosa from the middle ear.

2. Economics of Medical Organization, By J. MADISON TAYLOR
3. The Development of Fibroids of the Uterus After Ablation of the Appendages, By J. WESLEY BOVÉE
4. A Case of Typhoid Perforation of the Intestine with Surgical Treatment and Recovery, By THOMAS W. HUNTINGTON and GEORGE B. EBRIGHT.
5. Stenosis of Pylorus in Infancy, an Analysis of One Hundred and Fifteen Cases (*To be continued*), By CHARLES L. SCUDDER.
6. Ankylosis. Arthroplasty—Clinical and Experimental (*To be continued*), By JOHN B. MURPHY.
7. Tolerance to Nitroglycerin, By D. D. STEWART.
8. Peritoneal Gauze Drainage. An Easy Method of Its Use Through the Vagina, After Abdominal Section, By W. D. HAGGARD.
9. Immunity. Chapter XVI (*To be continued*).

1. **Infant Feeding.**—Churchill asserts that cases of difficult feeding in infancy are cases of (a) fat indigestion, (b) sugar indigestion, (c) proteid indigestion. Each one of these varieties may exist alone or in combination with the others. The most frequent form is proteid indigestion, but cases of fat indigestion are also common. Each individual infant must be a law unto himself. Babies cannot be fed by rule of thumb. The form of indigestion present, if possible, must be

determined and appropriate treatment applied. The treatment is almost exclusively dietary. The fats and sugar can be regulated by varying the amounts of cream and sugar. The composition of cow proteid, high caseinogen, and low lactalbumin, must be remembered in the management of proteid cases. The caseinogen must often be cut to a low point or even eliminated altogether; lactalbumin must be retained in the food; this twofold object is attained by feeding whey. Increase in quality and quantity of the food must be made gradually. It is desirable that many artificially fed babies should be carefully studied, the symptoms of different forms of indigestion noted, and the data published.

3. **Uterine Fibroids.**—Bovée asserts that, in the absence of a better explanation, he is disposed to accept the theory that fibroid tumors of the uterus, which originate after ablation of the appendages, owe their origin to an obliterating endarteritis. The proof of this is not very satisfactory, but for the present no better theory exists.

7. **Nitroglycerin.**—Stewart asserts that a tolerance for nitroglycerin is easily acquired. He once had a patient who took as much as 20 minims of pure nitroglycerin a day without inconvenience. Lately the author has not been using as large doses of the drug as he formerly did, and believes that it is rarely necessary to go beyond ten drops of a one per cent. solution a day.

BOSTON MEDICAL AND SURGICAL JOURNAL.

May 25, 1905.

1. A Consideration of the Pelvic Articulations from an Anatomical, Pathological, and Clinical Standpoint, By JOEL E. GOLDTHWAIT and ROBERT B. OSGOOD.
2. A Case of Foreign Body in the Œsophagus, By A. COOLIDGE, JR.
3. Conservative Operation on the Ovaries and Tubes: Analysis of Ninety Cases, By R. G. WADSWORTH.

1. **The Pelvic Articulations.**—Goldthwait and Osgood have made, and now report a most elaborate study of the articulations of the pelvic bones. The general subject of relaxation of these articulations was first forcibly brought to Goldthwait's attention by seeing a patient who suffered great disability, due to marked relaxation of the pelvic articulations following pregnancy. Since that time the authors have had this condition in mind, have studied its anatomy and pathology, and have had the opportunity of observing over one hundred patients suffering from symptoms referable to these articulations. As the cases are studied they at once divide themselves into groups; the first including the cases in which there is definite relaxation associated with pregnancy, representing an exaggeration of a normal physiological condition; the second the cases in which the relaxation is associated with menstruation, apparently representing also a physiological condition, apart from any pathological change with which we are at present familiar; and the third, the cases in which the lesion is due to trauma, general weakness, or some definitely known pathological process. The cases in the first two groups are

naturally all women. In the last group sex and age do not influence the condition. It is not possible to follow the authors in their minute description of the anatomy, pathology, symptomatology, and treatment of the condition. Very briefly, and inaccurately, it may be said that many cases of backache, especially the kinds that come on at night during muscular relaxation, are due to this condition and that treatment consists essentially in fixing the pelvic bones, particularly the sacrum, by means of a special harness or plaster dressing. A number of illustrative cases will appear in the next issue.

2. **Foreign Body in the Œsophagus.**—Coolidge reports the following case: A woman swallowed an open safety pin. It lodged in the œsophagus, point up. The point became imbedded in the tissues and efforts at extraction, at the first attempt, had to be abandoned. The author had a metal ring, of suitable diameter welded at a right angle to a stiff wire. A Killian tube was passed into the œsophagus and through it the ring which was carried down below the pin. A Killian forceps grasped the pin by its point, pushed it down through the ring and so closed it. Extraction was then accomplished without further trouble.

3. **Conservative Operations.**—Wadsworth's ninety cases were operated in by various men at the Free Hospital for Women, Boston. He summarizes the results thus: "Considering the cases together without regard to the extent or multiplicity of operation, partial or complete symptomatic relief has been obtained in 86.5 per cent. Multiple operations give less good results as a whole than operations on the appendages alone, there being half again as large a percentage of failures in the former class. When both ovaries are cystic and part of one or both are saved, the chance of secondary operation for recurrence of cystic disease is nearly three times as great as in those cases where one normal ovary is present. Subsequent pregnancy has occurred in 26.5 per cent. In estimating the likelihood of this occurrence in any given case, it may be stated that the fact that the patient has borne children before operation nearly triples the chance of subsequent pregnancy."

MEDICAL NEWS.

May 27, 1905.

1. Clinical Features and Treatment of Epidemic Cerebrospinal Meningitis, By FRANCIS HUBER.
2. Infantile Tuberculosis: Its Portal of Entry, Topography, and Clinical Manifestations, By ROWLAND GODFREY FREEMAN.
3. Two Unusual Cases of Gastric Cancer, By WILLIAM FITCH CHENEY.
4. The Present Clinical and Bacteriological Status of Vincent's Angina, By WILLIAM N. BERKELEY.
5. On the Widal Reaction, By E. ANDRADE.

1. **Meningitis.**—Huber analyzes the clinical symptoms of the one hundred and twelve cases of epidemic cerebrospinal meningitis that were treated at the Gouverneur Hospital in 1904. To

give a composite picture of the symptomatology of the disease, as it was observed by the author, would result in a description varying little from that to be found in the ordinary text book; a manifestly useless task. The mortality was between sixty-five and seventy per cent. The treatment was essentially symptomatic, and no new specific methods are advocated.

2. **Infantile Tuberculosis.**—Freeman's paper is based on one hundred and fifty-eight autopsies of tuberculous patients performed at various hospitals. The author's summary of his paper, condensed, follows: "Tuberculosis in infancy arises most often from an infection through either the respiratory or alimentary tract; the comparative frequency of these two modes of infection has not yet been definitely determined. The tuberculosis of early life is most common during the first year, when children are on an exclusive milk diet. At this period, owing to the structure of the intestinal wall, bacteria can probably pass through it. Experiments on animals show that inhalation tuberculosis causes usually lesions of the bronchial lymph nodes and lungs alone, while whatever the portal of entry these structures become very early involved. Inoculation experiments prove that the mesenteric lymph nodes may be tuberculous without the presence of any gross lesions in them. Twenty-six and one half per cent. of the 158 autopsies show intestinal or mesenteric lesion on gross examination. The tuberculosis of infancy is usually an acute, widely disseminated, general disease, with moderate temperature and few symptoms and physical signs unless the invasion of the meninges gives rise to symptoms. Tuberculosis of the cervical lymph nodes and of the joints is rarely seen under the third year. The power to overcome a tuberculous infection that has spread from the lymphatics and invaded the organs apparently does not exist in infancy. While the autopsies show a very wide distribution of the tuberculous disease, they probably indicate a much less general distribution than really existed, for the data are based often on hurried gross examination without microscopic confirmation."

3. **Gastric Cancer.**—Cheney's two cases, very briefly summarized, are: (1) No symptoms referable to the stomach. Failing health for some months. After a time the liver was found to be greatly enlarged. At first the case was thought to be one of syphilis of the liver. The patient gradually grew worse and an exploratory incision was resorted to. Patient died shortly afterwards. Autopsy: Primary carcinoma of the stomach with secondary growth in liver. (2) No serious symptoms referable to the stomach. Failing health for some months. A mass in the region of the spleen which was at first thought to be an enlargement of that organ. Practically normal temperature. Anæmia and general weakness progressive, in spite of treatment. Aspiration of splenic tumor negative. Exploratory incision revealed a large abscess which was drained. Patient eventually died. Autopsy revealed perforation of the stomach, due to carcinoma and a peri-

gastric abscess consequent on the perforation. There were many metastatic carcinomatous foci.

4. **Vincent's Angina.**—Berkeley holds that Vincent's angina occurs more frequently than is generally supposed. It is most frequently confounded with syphilis and diphtheria. A positive diagnosis is easily made by staining slides with carbol fuchsin. The author has seen twenty-nine cases of the affection and asserts that when one is once familiar with its clinical aspect a fairly accurate diagnosis may be reached without the microscope. The author reviews the history, symptomatology, pathology, bacteriology, and treatment of the disease.

5. **Widal Reaction.**—Andrade, after making three hundred tests of the Widal reaction with both living and dead cultures, and using dried blood, reaches the following conclusions: (1) Living and dead cultures are about equally sensitive to the action of the agglutinins of typhoid fever, though in dead culture the reaction may require a longer time to take effect, and it is therefore necessary to keep the specimen under observation for two hours. In some cases the reaction is quicker with the dead than with the living cultures. (2) The dried blood method is equally effective with dead as with living cultures. (3) The reaction, when it takes place, is more characteristic with dead cultures than with living cultures. There are no pseudoreactions with dead cultures. (4) Dead cultures do not seem to lose their sensibility to the agglutinins of typhoid fever for a long time. He has now in use a dead culture which was prepared six months ago, and it reacts just as typically as when first used.

MEDICAL RECORD.

May 27, 1905.

1. Intermittent Claudication and Allied Syndromes, Due to Arteriosclerosis of the Extremities,
By J. RAMSAY HUNT.
2. The Gardener's Spade Deformity and the Silver Fork Deformity in Fractures of the Carpal End of the Radius,
By JOHN B. ROBERTS.
3. My Changes of View in Appendicitis Work,
By ROBERT T. MORRIS.
4. Toxæmia of Intestinal Origin as a Condition Predisposing to Minor Infections,
By HARRIS A. HOUGHTON.
5. Responsibility in Mental Deformity,
By JAMES WEIR, JR.

1. **Intermittent Claudication.**—Hunt summarizes his views as follows: Arteriosclerosis of the extremities in its gravest form, uncomplicated by a vasomotor neurosis leads to spontaneous gangrene. If the arteriosclerosis occurs in combination with a vasomotor instability and a tendency to vasomotor spasm, the syndrome of intermittent claudication results. This is characterized by the development of sensory (pains and paræsthesia), and motor (weakness and rigidity) manifestations during functional activity with a rapid and permanent restoration to the normal during rest. The syndrome, however, has a wider and more general application to the whole

circulatory mechanism and has been observed in relation to various organs of the body (heart, intestines, brain, kidney, and eyes).

2. **Fractures of the Lower End of the Radius.**—Roberts asserts that notwithstanding the fact that so much has been recently written regarding fractures of the lower end of the radius the lesion continues to be very badly treated by a great number of practitioners. The essential for a good result is forcible reduction, and it is this forcible reduction which is usually neglected. 'Almost any simple dressing will maintain reduction, though plastic splints are to be preferred to wooden ones.

3. **Appendicitis.**—Morris reviews the evolution of his technics for the treatment of appendicitis. The chief points to be emphasized are, perhaps, these: A small incision by the gridiron method; removal of the appendix in all cases (abscess cases included) except perhaps when the patient is moribund; no flushing of the peritoneal cavity; no gauze packing. The author has returned to the method of using a cigarette drain in all cases in which pus or septic debris is left in the peritoneal cavity, but the wound is closed without drainage in cases in which gangrene and pus occur within the peritoneal coat of the appendix.

AMERICAN MEDICINE.

May 27, 1905.

1. Of Ailurophobia and the Power to be Conscious of the Cat as Near, When Unseen and Unheard,
By S. WEIR MITCHELL.
2. Observations Upon Amœbas Infecting the Human Intestine, with a Description of Two Species, *Entamœba Coli* and *Entamœba Dysenterizæ* (*To be continued*),
By CHARLES F. CRAIG.
3. Chylous Ascites,
By JAMES FINLEY BELL.
4. Some Results of Abdominal Operations,
By GEORGE EREY SHOEMAKER.
5. The Lloyd Reaction for Morphine and Other Alkaloids (*To be continued*),
By DANIEL W. FETTEROLF.
6. Acute Carbon Bisulphide Poisoning,
By ALBERT PHILIP FRANCINE.
7. The Physician as a Citizen (*To be continued*),
By EDWARD N. BRUSH.

1. **Ailurophobia.**—Mitchell's request, made in *American Medicine*, for information regarding ailurophobia and the power to be conscious of the cat as near, when unseen and unheard, received one hundred and fifty-nine answers, of which about one third were valueless. A careful study of the replies with much subsequent inquiry and experimentation has led him to conclude that emanations from cats, odorous to some, may in others cause emotional disturbance without so impressing the olfactory nerves as to be recognized as odors. Persons who suffer from cats may be thus classed: "(1) Asthmatics—cat asthma. (2) Cat fear, with or without sequent, excessive, emotional manifestations, and only on sight. (3) Cat fear. Power to be sure an unseen cat is near. Symptoms same as in class 2, and apt to be extreme. (4) Those of the last class can detect the cat by smell, or may sometimes and

not always. (5) Cases occur in which the consciousness of a cat as present through its smell once existed, but does not now, and yet the ability to detect unseen cats remains. (6) It is therefore likely that the cat emanations may affect the nervous system through the nasal membrane, although unrecognized as odors. Why these emanations should, if plainly perceived as due to cats, cause certain symptoms in those who dread cats, is readily understood. The ultimate cause of unreasonable terror of cats, I cannot explain. To be told that a cat is near when none is in the room, may occasion the same unpleasant consequences as when the cat is present. It is, perhaps, worthy of note how many of the victims of cat fear declare that even strange cats seem to have an unusual desire to be near them, jump on their laps, and follow them."

3. **Chylous Ascites.**—Bell reports one personal case in detail. He has tapped his patient 37 times and removed 272,365 cubic centimetres of chyle since the first of last October. It is remarkable that the patient as yet has lost little in weight and strength, though he suffers much from the distention and from shortness of breath. The literature of chylous ascites is reviewed and a table of the thirty-three cases so far reported is given. To the paper is appended a report by Dr. Walter Kent on the chemical examination of portions of the fluid removed from the author's patient.

4. **Abdominal Operations.**—Shoemaker analyzes one hundred consecutive abdominal sections performed by him at the Presbyterian Hospital. We note that, as a general rule, the author prefers dry sponging to flushing, and only uses drainage in exceptional cases.

6. **Carbon Bisulphide Poisoning.**—Francine reports one case. As he only saw his patient once the history of the case is quite brief. The symptoms presented were in a general way those typical of carbon bisulphide poisoning.

BRITISH MEDICAL JOURNAL.

May 13, 1905.

1. The Logical Basis of the Sanitary Policy of Mosquito Reduction, By R. ROSS.
2. The Cause and Treatment of Pruritus Ani, By F. C. WALLIS.
3. The Surgical Anatomy and Operative Treatment of Tuberculous Glands of the Neck, By W. G. SUTCLIFFE.
4. Congenital Hypertrophy and Dilatation of the Sigmoid Flexure, By W. F. BROOK.
5. The After-History of Patients Upon Whom Gastric Operations Have Been Performed, By C. M. MOULLIN.
6. The Value of the Vermiform Appendix in the Treatment of Ulcerative and Membranous Colitis, By J. HUTCHINSON, JR.

1. **Destruction of Mosquitoes.**—Ross bases his conclusions on the following arguments: 1. There must be for every living unit a certain distance (limit of migration) which that unit may possibly cover if it continues to move all its life

always in the same direction. 2. Owing to the constant changes in direction which must take place in all random migration, the large majority of units must tend to remain in or near the neighborhood where they were born. 3. Applying this reasoning to the particular case of the immigration of mosquitoes into an area in which their propagation has been arrested by drainage and other suitable means, the following conclusions are reached: 1. The mosquito density will always be reduced, not only within the area of operations, but to a distance equal to the ideal limit of migration beyond it. 2. On the boundary of operations the mosquito density should always be reduced to about one half the normal density. 3. The curve of density will rise rapidly outside the boundary and will fall rapidly inside it. 4. As immigration into an area of operations must always be at the expense of the mosquito population immediately outside it, the average density of the whole area affected by the operations must be the same as if no immigration at all has taken place. 5. As a general rule for practical purposes, if the area of operations is of any considerable size immigration will not very materially affect the result. The whole subject of mosquito reduction cannot be scientifically examined without mathematical analysis.

2. **Pruritus Ani.**—Wallis's remarks apply to the inveterate cases of pruritus ani, which go on year after year, and bring in their train other symptoms, due to want of sleep, dyspepsia, etc. The local appearance of the skin is quite typical, and should be recognized as pathognomonic. The chronic inflammation of the epidermis completely alters its character, which becomes largely infiltrated with fibrous tissue, loses its elasticity, and becomes covered with dead and sodden epithelium. In ninety per cent. of his cases the author has found a shallow ulcer situated between the two sphincters, generally in the posterior segment and near the dorsal midline. In some cases there is more than one ulcer. He believes the method of fusion of the proctodæum with the blind end of the gut is the cause of this frequent ulcer. The thin mucous membrane is readily abraded and ulcerates. The author obtains the best results by following out this treatment; the patient is anesthetized and put in the lithotomy position. The sphincter is moderately stretched and the ulcer or ulcers brought into view and treated with the electric thermocautery, and the cautery is also applied to the thickened skin as well, especially where fissures or clefts exist. Vaseline is applied to the cauterized area, and a morphine suppository inserted into the bowel. A pad of wool is kept in position by a T bandage, and the patient is put back to bed and kept there. A purge is given on the third night. The irritation usually ceases either at once or after a few days, and the patients are well in about fourteen days. Where the abrasion practically encircles the bowel, he dissects off the ring of tissue involved. The interesting feature is the immediate cessation of irritation after the cautery has been applied.

3. **Tuberculous Glands of the Neck.**—Sutcliffe gives a detailed description of the surgical anatomy and operative treatment of tuberculous glands of the neck. Enlarged tuberculous glands rarely disappear without operative treatment after they have existed as definite palpable tumors for more than six months. The main contributory causes of such a result are always the climatic and hygienic conditions, and to these must be added prolonged rest. In the following four sets of cases operation should be carried out at once: 1. Where suppuration is taking place; (2) where sinuses, as a result of burst abscesses or previous incomplete operations, are present; (3) where, though not obviously suppurating, the glands are increasing in size, are causing pain, uneasiness, and deformity, and have not yielded to hygienic and climatic measures; (4) where gland infection has occurred in subjects unable or unwilling to incur a prolonged period of rest, or whose future would be jeopardized by the interruption of their education, or by the presence of the glands, as in boys wishing to enter the public service.

4. **Congenital Hypertrophy of the Sigmoid Flexure.**—Brook states that so called idiopathic dilatation and hypertrophy of the colon (Hirschsprung's disease), though not infrequent is seldom recognized during life. It occurs most frequently in early childhood, the symptoms usually commencing within a few days of birth. These are constipation with abdominal distention sometimes reaching enormous proportions, and more or less frequently recurring attacks of intestinal obstruction, the general health being often seriously affected by intestinal autointoxication. In well marked cases there is in addition to a permanently enlarged and lengthened abdomen, marked deformity of the thorax which is shortened and widened, so that the lower ribs lie horizontally and the subcostal angle is widely opened out. The disease is more common in males than in females. Death takes place from various causes—obstruction, colitis, syncope, or perforation—but a certain number reach adult life. The distention is entirely due to enormous dilatation with elongation of the colon, especially the sigmoid. The muscular coats are greatly hypertrophied. The rectum is generally normal and no organic obstruction is found to account for the condition. The author reports the case of a young woman, aged twenty-one years, suffering from this condition. There was a hard, globular, and movable tumor, dull on percussion, rising out of the pelvis somewhat to the left of the middle line. On opening the abdomen the colon was found to be enormously enlarged and thickened, and it contained a large concretion composed of vegetable fibre. This was removed, the bowel narrowed down by sutures, and the patient made an uneventful recovery.

6. **Ulcerative Colitis.**—Hutchinson reports a case of ulcerative colitis, occurring in a man, aged thirty-six years. It was treated by means of irrigation through the vermiform appendix—a lotion of nitrate of silver being the fluid used. The

patient, who had been admitted to the hospital with a diagnosis of malignant disease of the colon, was discharged well nine weeks later. By using the appendix for irrigation purposes, all leakage of cæcal contents can be avoided; by means of a rubber catheter inserted and retained in the appendix, the washing out of the colon can be done in an efficient and cleanly way; and, finally, it is quite easy by resection of the appendix to close the fistula when the treatment has accomplished its object.

LANCET.

May 13, 1905.

1. A Case of Concealed Menstruation; with Remarks on Treatment, By P. HORROCKS.
2. Nutrition and Malnutrition (*Lumleian Lectures, II*), By W. H. ALLCHIN.
3. A Case of Splenomegalie, or Myelopathic Polycythæmia, with True Plethora and Arterial Hypertonia Without Cyanosis, By F. P. WEBER.
4. *Symptomatologie et Diagnostic de l'Angine à Spirilles et Bacilles Fusiformes (Angine de Vincent)*, By H. VINCENT.
5. Treatment of Complete Uterine and Vaginal Prolapse, By F. H. WIGGIN.
6. Carcinoma of the Uterus and Its Surgical Treatment, By E. T. THRING.
7. The Technics of the Operation for Adenoids and Enlarged Tonsils, with Some Practical Suggestions, By F. C. CARLÉ.
8. Anatomical Peculiarities of a Gall Bladder on Appendix, By F. LEMON.
9. Cæsarean Section for Congenital Malformation of the Cervix Uteri; Recovery, By H. T. SKAE.

1. **Concealed Menstruation.**—Horrocks says that concealed menstruation must be looked upon as a rare condition. Probably imperforate hymen is the commonest cause of it, but it may result from congenital or acquired atresia of any part of the parturient canal, e. g., from the os internum of the uterus. In imperforate hymen the opening is filled in by a membrane. When the menses first appear they flow into the vagina, a portion being absorbed before the next period, and a portion remaining. As time goes on this remainder grows until the vagina is distended with a dark treacly fluid which generally remains aseptic. This is known as hæmatocolpos, and is free from danger no matter how relieved. But if the imperforate hymen does not yield and the concealed menstruation continues, the uterus gradually gets distended, a condition of hæmatometra is superadded, and the uterus and vagina form one large common cavity. If unrelieved the Falloppian tubes become distended and so a hæmatosalpinx results. If the blood in the uterus becomes septic it, as a rule, contaminates that in the tube or tubes. Finally the blood may escape into the peritoneal cavity, causing a hæmatocele, or burst into the broad ligament, causing a hæmatoma. As long as a patient with concealed menstruation remains unrelieved, she is in danger of septic infection or of rupture of the vagina, uterus, or tubes. The former is by far the more common, and often causes death. The author reports a case of hæmatocolpos which was correctly diagnosed, and

a tiny puncture made in the bulging membrane, two quarts of treacly fluid escaping. The uterine contents became infected, however, and passing through the tube, infected the peritonæum, necessitating operation, removal of one ovary and tube, and frequent and thorough douching in order to save the patient's life. What should always be done is to incise the membrane and wash out the cavity thoroughly. Since his adoption of this line of treatment the author has never lost a case.

2. **Nutrition.**—Allchin, in the conclusion of his second Lumleian lecture, sums up as follows: The vital activities of the living cells seem to consist essentially in the formation of ferment bodies which alone or in combination effect those integrations and disintegrations which liberate chemical energy, and this by transformation produces muscular work, nerve force, and secretory function, the fundamental manifestations of life. That these enzymes do bring about these changes in such conditions of temperature and alkalinity or acidity as obtain in the body appears to be certain; and as an explanation of the bioplasm which elaborates these bodies there is postulated an ionic action on the part of the cell contents and their surrounding medium whereby charges of electricity of variable strength and character are brought into conflict and that from the play of ions the manifestations of vitality result. Such a conception of bioplastic activity leads more clearly to the realization of the inseparable unity of function and nutrition, and that nutrition in its fullest sense is life itself.

3. **Splenomegalic Polycythæmia.**—Weber reports the case of a woman aged thirty-seven years who, when first seen, was suffering from erythromelalgia. Later the case was found to be one of splenomegalic or myelopathic polycythæmia, differing only from those reported by Osler and others, in that cyanosis was absent. The diagnosis was based on enlargement of the spleen, true plethora (polyhæmia), and arterial hypertension. The author believes the order of development of the main symptoms and their causal connection to be as follows: 1. Increased erythroblastic activity involving a great part, but not necessarily the whole, of the bone marrow. 2. Increased viscosity of the blood resulting from the polycythæmia. 3. Dilatation of small blood vessels, partly to lessen resistance to the abnormally viscous blood, partly to make more room for dilution of the blood. 4. The plethora vera or polyhæmia is to be regarded as an attempt to compensate for the increased viscosity of the blood and for the excessive percentage of the total blood volume occupied by the cells. It is necessary that there should be sufficient blood plasma to nourish the tissues and make metabolism possible; and that the viscosity may not become so great as to render sufficient circulation impossible. 5. The arterial hypertension is to be regarded as a result of the greater strain thrown on the circulatory mechanism. 6. Cyanosis, when it occurs, is probably due to inadequacy of the series of compensatory changes which precedes it. The patho-

logical activity in the erythroblastic function of the bone marrow may be the result possibly of tumor formation in the marrow, or to the presence of a hæmolytic toxine in quantities just sufficient to cause reaction. The splenic enlargement seems to be due merely to increase of the pulp and engorgement with blood.

7. **Adenoids.**—Carlé calls attention to the following practical points in connection with the operation for the removal of adenoids and enlarged tonsils. The patient should be in a horizontal position in the dorsal decubitus, with the head neither flexed nor extended. In removing the tonsils a small amygdalatome should be used in preference to a large one, since the encircled organ is not so liable to slip out. It is important to get the lower edge of the instrument below the lower end of the tonsil—thread the ring on to the tonsil from below upwards. The posterior pharyngeal wall is best cleared at the end of the operation by scraping with the finger nail from below upwards, thus avoiding tearing downwards of the posterior pharyngeal wall as is liable to follow the use of a curette. Large buried tonsils are best dealt with by removing a thin slice, followed by breaking down of the tonsil tissue with the finger. The cicatricial contraction following this method of procedure markedly reduces the size of the hypertrophied organ.

Letters to the Editor.

ALKALINE BEVERAGES IN THE TREATMENT OF PNEUMONIA.

1635 LOCUST STREET,
PHILADELPHIA, May 28, 1905.

To the Editor,

Sir: In an article entitled Alkaline Beverages in the Treatment of Pneumonia (*New York Medical Journal*, May 20, 1905), by Dr. J. B. Todd, of Syracuse, N. Y., there is an error which it is my duty to correct. In speaking of the employment of saline substances in pneumonia Dr. Todd states that "at first they were used per rectum as suggested by Dr. F. P. Henry, of Philadelphia, in 1889." I made no such suggestion in 1889 or at any time since that date. In 1889 I employed, and have ever since advocated by writing and teaching, *saline hypodermoclysis* in the treatment of pneumonia. This is, of course, the most direct and, in my opinion, much the most efficacious method of administering saline substances in pneumonia. My principal articles on the subject are: Treatment of Pneumonia by Hypodermoclysis (*International Clinics*, Vol. IV, ninth series, 1900); Remarks on the Treatment of Pneumonia (*Philadelphia Medical Journal*, February 14, 1903); Saline Hypodermoclysis in the Treatment of Pneumonia (*Medical Chronicle*, Manchester, England, February, 1904).

Reference to my work may also be found on page 43 of the Transactions of the Association of American Physicians for 1894 (Vol. IX), in the course of some remarks on a paper of Dr. Beverley Robinson by Dr. James C. Wilson. The whole question of priority is ably discussed in the *Medical News* for July 6, 1901, and in view of the publicity which

has been given to the subject, a publicity not altogether of my own seeking. I am somewhat surprised at the error in Dr. Todd's paper.

While I care little about the honor of being first in the matter which is a small one in the course of my work, I call attention to it because I am a great stickler for accuracy. FREDERICK P. HENRY.

2043 WALNUT STREET,
PHILADELPHIA, May 23, 1905.

To the Editor,

Sir: In an article entitled *Alkaline Beverages in the Treatment of Pneumonia*, published in your issue of May 20, 1905, Dr. J. B. Todd, of Syracuse, introduces what I regard as a very important step in the successful treatment of this dread disease, i. e., the oral use of saline solution. The two cases selected to illustrate his results are very suggestive: In the first case, in a woman of eighty-four years, the solution was used from the start; in the second, in a child of eight years, the improvement coincided with the use of alkaline beverages.

Dr. Todd having been good enough to inform me that my work on the *Internal Secretions* had started his inquiry, I wish to express the earnest hope that his method of treatment be extensively tried. Some opposition to the use of saline solution in this and other diseases has been based on the fact that the sudden elimination of waste products tends to cause inflammatory renal lesions or to augment them if present. In truth, such lesions occur because the toxic wastes are allowed to accumulate in the organism; on being suddenly liberated when the saline solution is used, they overtax the kidneys. This is prevented when the saline solution, which facilitates and insures the gradual elimination of toxic waste products, is administered from the start. Dr. Todd's formula is admirably adjusted to this purpose and provides "a refreshing effervescent drink, which is gratefully accepted by the patient." It is as follows:

R Sodium chloride.....320 grains;
Potassium bicarbonate.....160 grains;
Aromatic fluid extract (U. S. P.).....30 minims;
Water, enough to make.....4 ounces.

M. A teaspoonful in six to eight ounces of water every two hours, with a teaspoonful of lemon juice.

The patient is also allowed to drink water at will.

Experimental bacteriology forcibly emphasizes the importance of an alkaline reaction of the blood fluids in disease. Behring and Nissen have shown that it is because of the intense alkalinity of their blood that rats are refractory to anthrax. Paul not only confirmed this observation, but found that when the alkalinity of the serum of rabbits was neutralized its germicidal powers disappeared; von Fodor found that the resistance of rabbits to anthrax could be actually increased by the injection of alkaline solution, and Blumenthal found that the formation of bactericidal agents coincided with the blood's alkalinity, etc.

The more advanced teachings of biology point in the same direction. "We know," says Jacques Loeb in his recently published *Studies in General Physiology*, "that the peculiar phenomena of oxidation in living matter are determined by fermenta-

tive processes, and we venture to say that fermentations form the basis of all life phenomena." Dr. Todd's article refers to my interpretation of the body's autoprotective processes, viz., that tryptase, a ferment—activated by the interaction of the blood's oxidizing substance (as catalytic) and the phosphorus-laden fibrinogen—underlies the bactericidal and antitoxic properties of the blood and cells. This view assimilates the immunizing attributes of the organism, not only to the digestive processes, but also to the "life phenomena"—all being regarded as "fermentations." Linked to this fundamental principle is another, however (a *sine qua non* of the intrinsic cellular interchanges), to which Loeb gives voice when he says: "The sodium ions of the blood as well as of the sea water are essential for the maintenance of life phenomena." Hence my conclusion that in febrile diseases there exists a close relationship between a deficiency of sodium and death.

Even under normal conditions nearly one half ounce of sodium chloride is excreted each day with the urine, the loss being constantly made up by the food, along with that of the potassium salts. But the altered conditions during toxæmias, reduced diet, impaired assimilation, anorexia, etc., greatly diminish the intake, and unless measures are taken to compensate for this the defensive functions are increasingly hampered and the chances of death are correspondingly increased. And this applies not only to pneumonia, but to all febrile toxæmias. Considerable work done since the first volume of *Internal Secretions*, etc., was written, and personal clinical observations have convinced me that we have in the judicious use of alkaline salts in all morbid processes of this kind an important life saving measure.

C. E. DE M. SAJOURS.

Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of April 12, 1905.

The President, Dr. JAMES M. ANDERS, in the chair.

(Concluded from page 1090.)

Dr. A. C. ABBOTT said that only upon the ætiological and epidemiological phases of the subject did he feel competent to speak. As to the former, he did not think the profession was in a position yet to say the final word. While he thought positively that the best contributions along this line had come from Councilman's laboratory, he was convinced that during epidemics there were occasionally cases, clinically like the majority of cases, and yet due to factors other than the organism designated by Councilman. There appeared to be a *Pneumococcus meningitidis*, which was recognized only by the modern method of lumbar puncture or found at autopsy. Dr. Abbott had seen none of the cases, but was told that occasionally cases were accompanied with influenza. The opinion was becoming prevalent that, as in the case of pneumonia, there were in-

dividuals going about harboring the organism which the profession regarded as the most productive factor of meningitis. It would look as if the widespread appearance of the disease might often be due to infections that were induced by some undetermined ætiological factor concerned with a corresponding outbreak of pneumonia. What that factor was had not yet been determined.

The transmissibility of the disease was the next point considered by Dr. Abbott. He thought the opinion was general that if the disease was transmissible at all, it was mildly so, and the experience of the Department of Health in Philadelphia had not been different from that of other observers. To the present time there had been reported at the Health Department since September fifty-eight cases of cerebrospinal fever, with eighteen deaths, a mortality of 31 per cent., and this was not allowing for erroneous diagnoses or doubtful cases. Of thirty-four histories, six cases were very doubtful and five were almost certainly tuberculous. Two of these were shown to be tuberculous by lumbar puncture, and two cases were found by lumbar puncture and autopsy to be due to the pneumococcus, so that out of the thirty-four there were thirteen which might be taken out of the original fifty-eight.

While it was not to be supposed that the transmission of the disease was impossible, Dr. Abbott believed from the records of outbreaks that the disease was very mildly contagious.

Dr. LONGCOPE, of the Pennsylvania Hospital, gave a review of the bacteriological work in acute meningitis in that institution in the past two years. In eighteen of such cases the spinal fluid had been studied. In four the pneumococcus was found and in twelve the meningococcus. There were excluded tuberculous cases, of which there were eight in which the tubercle bacillus was found. In one case the organism was found on the third day of the disease and in others on the fourth day. In 385 autopsies there were twenty-four cases of acute meningitis and fifteen of tuberculous meningitis. Six of these were due to either the streptococcus or staphylococcus and were secondary to scalp wounds, otitis media, or fractures of the skull. He referred to the conjunctiva as being an additional source from which the organism might be distributed. In one of the cases at the Pennsylvania Hospital there was severe purulent conjunctivitis in which the meningococcus was isolated. The case came to autopsy and the lesions were typical of acute meningitis and the organism was found again in the exudate.

Dr. FRANK WOODBURY thought that further experience would warrant the statement of Dr. Wilson in reference to the very mild communicability of the meningococcus from person to person. He believed that treatment should not be directed too markedly to the lesion in the nerve centres, the brain and spinal cord, because the disease was primarily a blood infection. He advocated the administration of such antiseptics as would be destructive to the meningococcus in the blood and wherever the blood would carry it into the brain and spinal cord. Such antiseptics were creosote,

guaiacol, beta naphthol, and other coal tar derivatives. It seemed to him possible that these cases might be favorably influenced by injections of formaldehyde into the blood.

Dr. NORMAN B. GWYN referred to his observation in 1899 of an epidemic of cerebrospinal fever. Eleven cases were attended in the hospital and seen frequently by doctors, nurses, and students, yet there was no development of the infection among the attendants. On the other hand, one of the patients gave the distinct history of having been twenty-four hours before in the barracks from which several cases of meningitis had been reported. Among the interesting observations of these cases there was seen the development of chronic cases in which a fever, typhoidal in type, with the temperature running to 105° or 106°, might persist for from five to seven weeks. In each case lumbar puncture was not only of value as a diagnostic measure, but of very material value in relieving the distress of the patients. Convulsive seizures were allayed as the fluid was drawn from the cord. In the bacteriological study the *Diplococcus intracellularis meningitidis* was obtained without difficulty in every acute case as it came into the hospital. As the case developed into the chronic stage it became more and more difficult to find the organism in the fluid. Blood cultures in one case demonstrated the presence of the meningococcus. In this case there was severe arthritis and the meningococcus was found in the joint fluid. In many cases the severe symptoms of meningeal irritation, such as rigidity, were relieved by immersion in hot water. In one case surgery was resorted to by Dr. Cushing. The needle brought away thick pus in which staphylococci were readily demonstrated. The spinal cord was opened and freely drained and the patient did remarkably well for some weeks, but died later from secondary infection of the fluid.

Dr. GWYN believed that the suggestion of the disease being a blood infection should be given more consideration, and thought it possibly due to this that surgical procedures had failed.

Dr. WILLIAM WADSWORTH spoke of the probable outbreak of meningitis following a similar infection in horses.

Dr. J. B. CROZER GRIFFITH spoke upon the subject from the aspect of the pædiatrist, and referred to the experience in the Children's Hospital. Each year brought to the hospital some cases of what might be called cerebrospinal fever. Though they have come in groups of two or three from a family, they were usually isolated, and all the types had been presented. There had never been a spread of the infection in the hospital, and the cases were not isolated. He emphasized the marvellous irregularity of the disease in type. He referred to one case outside the hospital which was absolutely typical. Another was fairly pneumonic, and in a third it would have been said there was present an ordinary pneumonia were it not for the observation of a little more rigidity and tendency to abdominal rash than should be expected.

Dr. A. E. ROUSSEL emphasized the fact that even in acute cases the *Diplococcus intracellularis* was not found on the first examination. In one case

in literature as many as three examinations were made before the organism was isolated. In subacute cases the organism was not found at all. In one case lumbar puncture was performed twice and in both instances negatively. The patient improved, but afterward passed into a chronic state. Death occurred outside of the hospital, and it was said that the post mortem was entirely corroborative of the diagnosis.

Dr. BOYER, of the Municipal Hospital, said that nine cases of cerebrospinal fever had been sent to the hospital since December, of which a full report would be made at some future time. In one case on the fifteenth day there was a leucocytosis of 49,000; on admission, the count was 17,600. One case showed a count of only 7,400. In seven cases the diplococcus was secured from the spinal fluid and from the nasal mucous membrane. Kernig's sign was present in all the cases. Three gave a positive Widal reaction. In none of these three was there any sign of typhoid fever. All had retraction of the head and stiffness of the back. Babinski's sign was frequently met with. The first symptom noted by the resident bacteriologist was anæsthesia of the conjunctivæ and generally of the corneæ. In several instances in which it was thought there were pressure symptoms lumbar puncture did not show excess of fluid. This, he thought, was due to the fulminant type of the disease. Reference was made to a case he had seen in Dublin which entered the institution as an acute case and became chronic. The anterior fontanelle of the child was not closed, and when there was an excess in the accumulation of fluid the fontanelle would bulge and the child become almost comatose. Lumbar puncture would relieve the child, who would take nourishment and even cry for food, to become comatose again at the end of a week or ten days. Of the nine patients in the Municipal Hospital, not one vomited while in the hospital. In one case there was marked keratitis and in one there was ulcer of the cornea. The latter showed the meningococcus.

Book Notices.

Exploration des fonctions rénales. Etude médico-chirurgicale. Par J. ALBARRAN, Professeur agrégé à la Faculté de médecine de Paris, Chirurgien des hôpitaux. Avec figures et graphiques en couleurs. Paris: Masson et Cie, 1905. Pp. 604.

In this volume there is an elaborate study of the physiology of the urine, based upon many original experiments, and also a complete exposition of the subject of modern cystoscopy, with methods for the separation, collection, and examination of the secretion of each kidney. In this part of the work due credit is given to the investigations and technique of Howard Kelly and Tilden Brown in this country. The author has devised a new method of testing the functional capacity of each kidney separately by producing an experimental polyuria. The book will be of interest to physiologists and of practical value to specialists in genitourinary surgery.

A Text Book of Diseases of Women. By CHARLES B. PENROSE, M. D., Ph. D., formerly Professor of Gynecology in the University of Pennsylvania, etc. With 225 Illustrations. Fifth Edition, Revised. Philadelphia: W. B. Saunders & Co., 1904. Pp. 550. (Price, cloth, \$3.75.)

Ever since its first appearance, in 1897, Dr. Penrose's work has been recognized as an acceptable exponent of conservative gynecology, and this edition seems to deserve the same recognition. While no startling changes have been made in the text, there is evidence throughout of such revision as time has rendered desirable.

Le Danger de la mort apparente sur les champs de bataille. Par le Docteur ICARD (de Marseille), vice-président de la Société de Londres contre le danger des enterrements prématurés, etc. Paris: A. Maloine, 1905.

The author has written a number of monographs on the subject of real and apparent death, and his enthusiasm has prompted him to investigate the danger of apparent death on the field of battle. As he truly states, there is no work on this subject; the reason is that in active campaigning the surgeons and the men of the hospital corps have their energies taxed to the utmost to care for the wounded, and there is neither time nor help to inspect all who are supposed to be dead to determine whether by chance any one is in a deathlike trance.

Ten Lectures on the Biochemistry of Muscle and Nerve. By W. H. HALLIBURTON, M. D., F. R. S., Professor of Physiology, King's College, London, etc. With Illustrations. Philadelphia: P. Blakiston's Son & Co., 1904. Pp. xvi-160.

This book contains an arrangement of the lectures that were given by the author at the University and Bellevue Hospital Medical College in 1904, and presents in a systematized way his many researches on muscle and nerve. The first five lectures are devoted to muscle, and describe the composition, heat, rigor, pigments, ferments, extractives and salts, and the chemical changes that accompany muscular contraction. The last five lectures describe the chemical composition of nervous tissue, its metabolism, the coagulation temperature of nerve proteids, the chemical pathology of certain degenerative nervous diseases, and the degeneration and regeneration of nerves. In the interesting investigation of fatigue it was demonstrable in the nerve centres and in the peripheral endings of nerve fibres; but the author thought that central fatigue was the more important and the more readily produced. He considers that sleep is the normal manifestation of one stage in the rhythmical activity of nerve cells, and though it may be preceded by fatigue or exhaustion, it is accompanied by repair, the constructive side of metabolic activity. He found that a temperature of 42° C. sufficiently long continued had the same influence as hyperpyrexia in causing coagulation of cell globulin. In the regeneration of nerve fibre he found that complete functional activity was associated with the appearance of the medullary sheath, just as the latter markedly shared in the degenera-

tive process when the nerve was cut. The author's style is forceful and clear and the book gives a comprehensive idea of these important subjects.

Diseases of the Liver, Gall Bladder, and Bile Ducts.

By H. D. ROLLESTON, M. A., M. D. (Cantab.), F. R. C. P., Physician to St. George's Hospital, London, etc. Fully Illustrated. Philadelphia: W. B. Saunders & Co., 1904. Pp. 794. (Cloth, \$6.00.)

This volume embodies the author's studies during the past twelve years of diseases of the liver from the clinical and pathological standpoints, and it includes some papers on these topics that have been published in journals and transactions.

The work is divided into sections on diseases of the liver, of the gall bladder, and of the bile ducts. In order that the bulk of the book should not be increased, the author has, and it seems wisely, omitted a review of the anatomy and physiology of the liver; and after describing anatomical abnormalities, some post mortem appearances, acquired deformities, and displacements of the organ, the various diseases are discussed with thoroughness and adequate detail.

The better authorities of the day will agree with the author that, while it is quite possible that primary functional disorder of the liver does occur, in the present state of our knowledge its existence is almost impossible to recognize with accuracy. The symptoms of such disorders are due to factors that interfere secondarily with the liver's functional activity, and not to primary functional failure of the organ.

The influence of dysentery on the etiology of single, or tropical, abscess of the liver is fully discussed, and it appears that there is no doubt that other organisms besides the ameba will cause hepatic abscess, but the latter is a frequent sequel of tropical dysentery.

The statement is made that it is rare to find sugar in the urine in ordinary cirrhosis; it has been an experience that the sugar, which, like the cirrhosis, is caused by alcoholic indulgence, will disappear under treatment and abstinence from alcohol.

The text is elucidated by clinical histories that add materially to its interest. The work is well printed, the photomicrographs are excellent, and the colored plates are good. There seems to be no satisfactory reason for the repetition of illustrations; Fig. 10 reappears as Fig. 26, and Fig. 38 as Fig. 47, and plate 2 has its illustrations inverted in plate 5, with changes in the legend. The reference in the second paragraph on page 41 to "p. 41" should be to page 37.

Transactions of the New Hampshire Medical Society at its One Hundred and Thirteenth Anniversary, held in Concord, May 19 and 20, 1904. Concord, N. H.: The Rumford Press, 1904. Pp. 317.

This volume contains the papers that were read at the one hundred and thirteenth anniversary, held in 1904. Among the interesting essays are one on albuminuria in the apparently healthy, by Dr. Leith, and a prize essay on the sanatorium treatment of incipient pulmonary tuberculosis, by Dr. F. L. Hills.

Miscellany.

First Aid in the British Navy.—It is a curious fact, observes the *Army and Navy Journal*, for May 6, 1905, that it is only at this late day that the British Admiralty has resolved to instruct the enlisted men in the navy in first aid service. In many large British warships launched in recent years little or no attention was given to arrangements for caring for the wounded in battle, but a commission has been appointed which is preparing to provide first aid instruction for men of all ratings on board ship and to consider the whole question of the most convenient places for surgical operations and the storage of surgical instruments and supplies. The *Hampshire Telegraph*, published at Portsmouth, England, says that as the result of suggestions made by that committee from time to time many wise changes have been effected in the internal arrangements of recent ships. Stations have been allotted for the surgeons behind armor or below the armored deck, where they would be sure of protection, while to facilitate the bringing of wounded men either up from the engine room or down from the gun positions on the upper decks, the hatchways have been made larger and fitted with specially designed lifts. The ash hoists have been increased in size so far as the engine rooms are concerned, and a chair and belt so designed as to easily accommodate injured men has now been provided for the ash hoists. Facilities, too, are to be provided for the prompt removal of the wounded, after treatment by the surgeons, to the sick bay and washing places, which, in time of action, would be fitted up as temporary hospitals.

Medical Ignorance of the Laity.—Of course it is not expected or even desired that every layman shall be as thoroughly conversant with medical topics as is the doctor. Nor is it possible that they can be more than superficially acquainted with any of the causes of ill health if they pursue their own vocations with the diligence it usually requires to promote any enterprise successfully. But ignorance is comparative, and the ignorance in some localities as compared with others is so obvious that the wonder is what causes this lack of progression.

Did you know, asks the *Medical Standard*, for February, 1905, that, with some people, the "skin" of an egg, or stale human milk is an infallible method of drawing a boil to a "head?" That for cuts and bruises a simple emollient of tobacco juice would heal it by first intention? That in fevers the dirty, greasy wool of the sheep bound tightly around the child is most efficacious in terminating the "distemper?" That tying a camphorated string around the neck of a dog or human being troubled with fleas will prevent their slacking their thirst in the watering troughs of the eye and so exterminate them? Of course salt pork will stand for years as the great eradicator of lockjaw. And of course putting certain foul smelling compounds of sulphur in the manger of a distempered horse will exert its invaluable properties in all cases.

Who is responsible? The doctor and the medical profession at large. Simply stated, all of the

knowledge, or almost all, appertaining to therapeutics which the laity possess is inherited from the profession. To-day they repeat the teachings of the ages which are now historical.

But these are more or less harmless therapeutic interferences. In other localities there is a vicious awakening from superstitious beliefs of the last century. Here one frequently sees alarming symptoms of a little knowledge which is dangerous. People possessed of a family guide or doctor book containing recipes for measles, whooping cough, bronchitis, pneumonia, indigestion, puerperal fever, hæmorrhage, eczema, scabies, syphilis, etc., etc., make their diagnoses from the printed page and copying the names of the ingredients used in the treatment they bring home the separate packages containing the medicaments and proceed to mix them, becoming not only their own physicians, but their own pharmacists!

One can imagine what harm may be done when it is remembered that carbolic acid, belladonna, sabadilla, sweet spirit of nitre, tincture of iodine, and ammonia are household remedies, while morphine, strychnine, and arsenic are open to them as eradicators of rats! Almost any drug, in fact, may be obtained in the crude state from unsuspecting druggists, though not so much in the larger centres as in the country villages.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the period from May 20 to May 26, 1905:

Smallpox—United States.

Places.	Date.	Cases.	Deaths.
Dist. of Columbia—Washington.	May 13-20.	2	
Florida—Jacksonville.	May 13-20.	2	
Illinois—Chicago.	May 13-20.	2	2
Illinois—Galesburg.	Apr. 13-20.	1	
Kentucky—Covington.	May 13-20.	9	
Louisiana—New Orleans.	May 13-20.	4	
Four cases imported.			
Massachusetts—Lowell.	May 13-20.	2	
Michigan—Ann Arbor.	Apr. 29-May 6.	1	
Missouri—St. Joseph.	May 6-20.	40	
Missouri—St. Louis.	May 13-20.	5	
New Hampshire—Nashua.	May 13-20.	2	
New York—Kingston.	May 13-20.	1	
New York—New York.	May 13-20.	1	1
Ohio—Cincinnati.	May 5-15.	7	
Ohio—Toledo.	May 6-13.	1	
Pennsylvania—Altoona.	May 13-20.	1	Imported
Pennsylvania—York.	May 13-20.	12	
South Carolina—Greenville.	May 13-20.	4	2
Tennessee—Memphis.	May 13-20.	1	
Tennessee—Nashville.	May 13-20.	4

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending May 24, 1905:

- LONG, H. D., Assistant Surgeon. To proceed to Ellis Island, N. Y., and report to Surgeon G. W. Stoner for duty.
- MATHEWSON, H. S., Passed Assistant Surgeon. Granted leave of absence for two months from June 16, 1905.
- McCLINTIC, T. B., Passed Assistant Surgeon. To proceed to Berkeley Springs, and other points in West Virginia, for special temporary duty.
- MIRANDA, R. U. L., Acting Assistant Surgeon. Granted leave of absence for thirty days from June 1st.
- OLSEN, E. T., Assistant Surgeon. To proceed to Ellis Island, N. Y., and report to Surgeon G. W. Stoner for duty.
- ROEHRIG, A. M., Pharmacist. Granted leave of absence for five days from May 19, 1905, under paragraph 191 of the regulations.
- SPRATT, R. D., Assistant Surgeon. To proceed to Cleveland, Ohio, and assume temporary charge of the station during the absence on leave of Passed Assistant Surgeon H. S. Mathewson.
- STONER, G. W., Surgeon. Granted three days' leave of absence from May 17, 1905, under paragraph 189 of the regulations.
- WAKEFIELD, H. C., Acting Assistant Surgeon. Granted leave of absence for ten days from May 27th.

Board Convened.

Board convened to meet at San Francisco, Cal., May 19, 1905, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board—Surgeon G. M. MAGRUDER, chairman. Passed Assistant Surgeon D. H. CURRIE, recorder.

Appointments.

Dr. HENRY D. LONG, of Pennsylvania, and Dr. EGIL T. OLSEN, of Illinois, commissioned (recess) as assistant surgeons in the Public Health and Marine Hospital Service May 19, 1905.

Dr. CHARLES E. FISHER appointed acting assistant surgeon in the Public Health and Marine Hospital Service, for duty at Toledo, Ohio.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending May 27, 1905:

- BISPHAM, WILLIAM N., First Lieutenant and Assistant Surgeon. Reports as in temporary charge of the chief surgeon's office, Department of Colorado, during the absence of the chief surgeon on inspection duty.
- BORDEN, WILLIAM C., Major and Surgeon. Ordered to New York city to consult with architects regarding plans for the new Army General Hospital to be constructed in this city.
- BROOKE, ROGER, JR., First Lieutenant and Assistant Surgeon. Granted three months' leave of absence, to take effect about August 1, 1905.
- BROOKS, WILLIAM H., First Lieutenant and Assistant Surgeon. Granted leave of absence for two months and fifteen days.
- BUSHNELL, GEORGE E., Major and Surgeon. Granted fifteen days' leave of absence.
- BYRNE, CHARLES B., Colonel and Assistant Surgeon General. Relieved from duty as Chief Surgeon of the Department of the Missouri, and ordered to Manila, P. I.,

- for duty as Chief Surgeon of the Division of the Philippines.
- COLLINS, C. C.**, First Lieutenant and Assistant Surgeon. Granted three months' leave of absence, to take effect when relieved from duty in the Philippine Islands.
- COMEY, EDWARD T.**, Lieutenant Colonel and Deputy Surgeon General. Retired from active service at his own request on account of thirty years' service, to take effect July 1, 1905.
- CRAIG, CHARLES F.**, First Lieutenant and Assistant Surgeon. Ordered to accompany First Squadron, Thirteenth Cavalry, from Presidio of San Francisco, Cal., to Fort Riley, Kan.; upon completion of which he will return to the transport *Logan*.
- GIRARD, JOSEPH B.**, Colonel and Assistant Surgeon General. Relieved from duty in the Philippines Division, ordered to proceed by first available transport to San Francisco, Cal., and upon arrival there to report to the Military Secretary of the Army for orders.
- HUTTON, PAUL C.**, First Lieutenant and Assistant Surgeon. Leave of absence further extended fourteen days.
- JONES, PERCY L.**, First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Monroe, Va., and ordered to Fort Preble, Me., for duty.
- MCANDREW, P. H.**, First Lieutenant and Assistant Surgeon. Reports at Arcadia Rifle Range for temporary duty.
- McCULLOCH, C. C., JR.**, Major and Surgeon. Detailed as a member of the board of medical officers to meet at West Point, N. Y., for examination of cadets' graduating class, and other cadets, instead of Assistant Surgeon Ekwurzel.
- MEARNS, E. A.**, Major and Surgeon. Ordered to proceed from this city, where on leave, to Fort Sill, O. T., to accompany First Squadron, Eighth Cavalry, to Manila, P. I., and upon arrival to report to the commanding general of the Philippines Division, for assignment to duty.
- MURTAGH, JOHN A.**, First Lieutenant and Assistant Surgeon. Ordered to accompany Second Squadron, Thirteenth Cavalry, from the Presidio of San Francisco, Cal., to Fort Myer, Va.; upon completion of which he will return to his proper station.
- RICHARDS, R. L.**, First Lieutenant and Assistant Surgeon. Having recently arrived from Manila, P. I., will report at Fort Mason, Cal., for temporary duty during the absence of Assistant Surgeon Murtagh, and in addition to this duty, will act as attending surgeon and examiner of recruits at San Francisco, Cal.
- SHIMER, IRA A.**, Captain and Assistant Surgeon. Relieved from duty at Fort Niagara, N. Y., and ordered to report in person to the Secretary of War for further orders.
- TORNEY, GEORGE H.**, Lieutenant Colonel and Deputy Surgeon General. In addition to present duties at the Army General Hospital, Presidio of San Francisco, Cal., ordered to take charge of the chief surgeon's office, Department of California, during the absence of the Chief Surgeon on leave.
- TRUBY, WILLARD F.**, Captain and Assistant Surgeon. Relieved from duty at Fort Preble, Me., and ordered to Fort Niagara, N. Y., for duty.
- WEBB, WALTER D.**, First Lieutenant and Assistant Surgeon. Granted three months' leave of absence.
- Navy Intelligence:**
Official List of Changes in the Medical Corps of the United States Navy for the week ending May 27, 1905:
- ANDERSON, F.**, Medical Inspector. Ordered to report to the Command Officer, Marine Barracks, Washington, D. C., for duty at those barracks.
- BROWN, H. L.**, Assistant Surgeon. Detached from the Naval Station, Guantanamo, Cuba, and ordered to the *Texas*.
- CORDEIRO, F. J. B.**, Surgeon. Ordered to the *Yankee*, sailing from New York about June 7, 1905.
- GATEWOOD, J. D.**, Surgeon. Detached from the *Yankee* and ordered home to await orders.
- GRAYSON, C. T.**, Assistant Surgeon. Detached from the marine barracks, Washington, D. C., and ordered to the *Maryland*.
- HOYT, R. E.**, Assistant Surgeon. Detached from the *Texas* and ordered home to await orders.
- PUGH, W. S., JR.**, Assistant Surgeon. Detached from the *Prairie* and ordered to the naval station, Guantanamo, Cuba, with additional duty on the *Monongahela*, sailing from New York about June 2, 1905.
- SHAW, H.**, Assistant Surgeon. Detached from the *Yankee* and ordered home to await orders.
- STALNAKER, P. R.**, Assistant Surgeon. Ordered to the Naval Hospital, New York, N. Y.
- STOKES, C. F.**, Surgeon. Ordered to additional duty as a member of the Anatomical Board of the District of Columbia.
- WARNER, R. A.**, Assistant Surgeon. Ordered to the Naval Hospital, Philadelphia, Pa.
- WIEBER, F. W. F.**, Surgeon. Detached from the *Prairie* when put out of commission, and ordered home to await orders.
- ZALESKY, W. J.**, Assistant Surgeon. Detached from the Naval Academy and ordered to the *Yankee*, sailing from New York, June 7, 1905.

Births, Marriages, and Deaths.

Born.

WINGERSKY.—In Boston, Massachusetts, on Monday, May 8th, to Dr. A. S. Wingersky and Mrs. Wingersky, a son.

Married.

ANGLE—GARRETT.—In Danville, Virginia, on Tuesday, May 16th, Dr. James B. Angle and Mrs. Mary E. Garrett.

DAVIS—WETHERILL.—In Baltimore, Maryland, on Thursday, May 25th, Dr. W. A. Davis and Mrs. M. K. Wetherill.

LONGIEL—SMITH.—In Brooklyn, N. Y., on Tuesday, May 16th, Dr. Edward Longiel and Miss Lillian Smith.

PATTERSON—DAY.—In Mindanao, Philippine Islands, on Tuesday, March 28th, Dr. Robert Uri Patterson, United States Army, and Miss Eda Beryl Loraine Day.

SCHULTS—UNDERWOOD.—In Bowling Green, Ohio, on Tuesday, May 16th, Dr. John Ward Shults and Miss Eudora Florence Underwood.

Died.

ALTWATER.—In Baltimore, Maryland, on Monday, May 15th, Dr. Edward W. Altwater, in the sixty-ninth year of his age.

ASCH.—In New York, on Friday, May 19th, Dr. Jacob H. Asch, in the sixty-sixth year of his age.

ATTERBURY.—In Macon, Missouri, on Tuesday, May 16th, Dr. Charles Atterbury, in the seventy-ninth year of his age.

DICKINSON.—In Baltimore, Maryland, on Tuesday, May 23rd, Dr. Albert H. Dickinson, of Pennsylvania, in the seventy-seventh year of his age.

FISCHER.—In Pittsburgh, Pennsylvania, on Sunday, May 21st, Dr. Erwin Fischer.

GRIDLEY.—In Binghamton, N. Y., on Friday, May 19th, Dr. S. D. Gridley, in the seventy-second year of his age.

HARRIS.—In Pensacola, Florida, on Friday, May 19th, Dr. Hatten N. T. Harris, United States Navy.

HEWITT.—In Cincinnati, Ohio, on Wednesday, May 17th, Dr. S. M. Hewitt.

KLEINSCHMIDT.—In Washington, D. C., on Saturday, May 20th, Dr. C. H. A. Kleinschmidt, in the sixty-seventh year of his age.

LIME.—In Aberdeen, South Dakota, on Tuesday, May 9th, Dr. William M. Lime, in the eighty-fourth year of his age.

LOWENTHAL.—In Hoboken, New Jersey, on Sunday, May 14th, Dr. Ernst J. Lowenthal, in the ninety-second year of his age.

MILLER.—In Greenpoint, N. Y., on Monday, May 22nd, Dr. Maud Miller, in the thirtieth year of her age.

THOMPSON.—In St. Paul, Minnesota, on Monday, May 15th, Dr. J. W. Thompson, in the sixty-eighth year of his age.

XANTEN.—In St. Paul, Minnesota, on Tuesday, May 16th, Dr. Frank A. Xanten, in the fifty-second year of his age.

Lectures and Addresses.

THE MODERN DOCTOR.*

By A. JACOBI, M. D., LL. D.,

NEW YORK.

Our first medical traditions date back to the East Indies and Egypt; our first real knowledge is derived from Hellas, the mother of the world's culture. Even Hellas had no regular physicians until the period of Lycurgus. It is true that Homer eulogizes the man of healing, but medicine was mostly theocratic. Gods, demigods, and their priests healed the sick. It was Apollo who smote men and armies with infectious diseases, and again relieved and saved them. But as there were always those who were sick and injured, attempts to aid them were the results of sympathy. Herodotus tells us that in Babylon the sick person was carried to the market place and took his choice from among the various cures advised by the multitude. In Greece the temples of the gods in which the priest practised celestial fraud and secured terrestrial experience, the tablets on which individual ailments and remedies were collected accumulated a store of available advice. But the translucent sky of Hellas did not permit of a predominance of obscurantism; her shrewd politicians and profound philosophers would not be satisfied with the mental slavery engendered by credulity; in the absence of manifold knowledge of natural things they began to philosophize.

Empedocles taught a theory of affinities—he called them love and hatred—that regulated the globe, which was composed of four elements, viz.: air, earth, water, and fire. In the animal body these were represented in blood, mucus, and yellow and black bile, and laid the groundwork for a humoral theory, while Democritus and Epicurus established the first atomistic theory and the solidist pathology. In the last century before Christ this was elaborated by that learned and

popular Greek physician of Rome, Asclepiades. Hippocrates was brought up in the theories of Empedocles, but never was there a more observing, empirical, reasoning, and practical mind than his; never a warmer heart, a more ethical conscience, or an intellect freer from hypothetical or unfounded assumption.

Neither Aristotle nor Plato appreciated Hippocrates at his full value. Though the former had all and more than the learning of his period, he was too much of a theorist like Plato himself to understand or to follow the great physician in his empiricism and the observation of facts. But it was Aristotle, and after him Herophilus, and two centuries later Galen, who added immensely to the knowledge of anatomy. Thereby they created a foundation for surgery, which during the reign of the school of Alexandria nobody had the unscientific tendency, rather prevalent with us, to separate from medicine. Galen could have continued to be the idolized creator of medicine to our own times if he had been able to keep apart from the speculations of Greek philosophy and had clung to the Hippocratic method of observing without theorizing.

Still, his means for obtaining knowledge were limited. His anatomy is that of animals; the teachings of the Koran, centuries afterwards, were opposed to the study of *human* anatomy, and both Galen and the medicine of the Arabs, while adding profusely to what we should call clinical and pharmaceutical knowledge, fell short of being the elaborators of Hippocratic medicine. Still, Galen and Aristotle controlled the thinking of the world until the era of Bacon, for fifteen hundred years.

Such an unbounded influence is never exerted by a single man anywhere except in religion or in science. In politics the gradual evolution of a nation, or of mankind, is not governed by an individual. No Alexander, or Cæsar, or Charlemagne, or Napoleon, or much smaller men with only a single thought in their heads like Bismarck, could have shaped the world anew, if the social and political situation had not favored

* An address delivered at the commencement exercises of the Washington University Medical Department, St. Louis, Mo.

them. History made *them*, but in science single men may make history. So did Paracelsus when he discarded the yoke of Galen, who had reigned undisturbed 1,600 years. So, towards the end of the eighteenth century, did Morgagni, when he introduced anatomical thinking into medicine; Haller, when he taught the functions of different organs, mainly the muscles, and discovered the existence of sensitive nerves, and of the different directions of nerve currents. So did John Hunter, when he established pathological anatomy and experimentation—for that is what he founded when he preached the paradoxical text: "Do not think, try"; Jenner, when he laid the foundation of sero- and organotherapy; Bichat, when he created histology. That is what Virchow did—guided by his predecessors and by Schwann and Schleiden—when he fixed the throne of life in the invisible cell; or Pasteur, when forever he demonstrated the omnipresence and omnipotence of the unseen microbe. "The universe itself is narrow," says the poet, "when compared with the vastness of man's brain."

Still, the few centuries following the time of Bacon and of Paracelsus were barren in their effect on clinical medicine. Sydenham, Boerhaave, Van Swieten, and Peter Frank were great and influential, but the foundation of medicine was not sound, and wanton systems followed one another both in philosophy and medicine.

The clouded mental atmosphere produced two peculiar systems, the modifications of which claim our attention this very day. They were Mesmerism and Hahnemannism. Mesmer was not always a fraud. Contrary to most frauds he was learned, but his mind was always tinged with mysticism. His very inaugural thesis, on the influence of the planets on the human body (1766), betrays him. He sank so far as to treat diseases by animal magnetism at a distance. Our present fakirs are only shallow imitations.

Hahnemann began his career with a paper published in 1796. Within a few years he completed his teachings, the principal of which were as follows:

The only vocation of the physician is to heal; theoretical knowledge is of no use. In a case of sickness he should only know what is curable, and the remedies. Of the diseases he cannot know anything except the symptoms. There are internal changes, but it is impossible to learn what they are; symptoms alone are accessible; with their removal by remedies the disease is removed. Their effects can be studied in the healthy only. They act on the sick by causing a disease similar to that which is to be combated, and which re-

solves itself into this similar affection. The full doses required to cause symptoms in the well are too large to be employed as remedies for the sick. The healing power of the drug grows in an inverse proportion to its substance. He says literally: "Only potencies are homœopathic medicines." "I recognize nobody as my follower but him who gives medicine in so small doses as to preclude the perception of anything medicinal in them by means either of the senses or of chemistry." "The pellets may be held near the young infant when asleep." "Gliding the hand over the patient will cure him, provided the manipulation be done with firm intention to render as much good with it as possible, for its power is in the benevolent will of the manipulator." Such is the homœopathy of Hahnemann, which is no longer recognized in what is called homœopathy to-day.

A modern critic (Tagel) says of Hahnemann's teaching that "his new system, which was announced with ferocity, and appeared unintelligible and crude to a sound mind, could not but impress the multitude, which did not differentiate between one bad logic and the other. His contempt for actual observations and experience pleased the ignorant, his violent criticisms of everything preceding him appealed to the unschooled protestant mind; indeed, he compared his cause with the fight of Protestantism against Catholicism; his very violence tallied with the revolutionary spirit of the time; the mysticism of the medicinal power of a substance when reduced to an unthinkable minimum was an astounding exemplification of the superiority of the spirit over the body; the ridicule and persecution to which his teaching and his vehemence exposed him were claimed as martyrdom."

Moreover, the homœopaths had a real martyrdom. Some sixty years ago the regular profession of the United States turned against them with the same vehemence that was exhibited by Hahnemann himself and his first apostles. That was taken by the American public as unfair; it always takes the side of those who are or appear to be persecuted. From that time dates the success of homœopathy in America, and its conquest of the hearts and minds of a large portion of the public. That is why homœopathy had a longer life than any other system which was the outcome of any man's mere thinking or mere imagining. Indeed, all systems are of that origin—Stahl's, Brown's, Rademacher's, Thomson's, no matter whose. To-day, however, medicine has reached that period of evolution which no longer permits it to be called a system. Since it came to be studied like one of the natural sciences, like biology, there are no schools any

more, but simply medicine. Homœopathy also has undergone changes like everything mortal in its own ranks. We in New York know that better than most States. Twenty-five years ago there were in our city a hundred medical shingles with the title homœopath painted on them. I believe there has not been one these ten years. The examination papers of the State Board of Examiners are the same for all the three boards, with the exception of those questions which refer to *materia medica*. A goodly number of the practitioners who are called by the public by their former name never use it themselves; there is no doubt that many who graduated from a homœopathic college and are called homœopaths by the ever faithful ladies of the hotel piazzas are satisfied to be practitioners of medicine. And I have reason to believe that the time is not distant when there will be no school, no sect, but medicine only. If a practitioner, after having, by passing his examinations, satisfied the people of the State that he is competent, chooses with the consent of his patient to regulate his therapeutic measures to suit himself or his patient, that is his own taste or business. For remember what we have sworn to in our Hippocratic oath: "I will follow that system of regimen which according to my ability and judgment I consider for the benefit of my patient." But I believe firmly that in a short time we shall have one board of examiners in place of three, and one solid body of medical men willing and competent to fight for the welfare of the public against quackeries of all sorts.

In New York State we had year after year to convince the legislature that the claims of so called osteopathy and others just as pretentious but less aggressive than Christian Science were contrary to common sense and the interests of the people. When lately I read before the committee of the legislature the following alleged definition of osteopathy—it cannot be learned by heart—as contained in the bill in which they asked recognition and a special board of examiners—please to listen: Osteopathy, means that science or system of healing which treats diseases of the human body "by manual therapeutics for the vital remedial forces within the body itself, for the correction of misplaced tissue and the removal of obstructions or interferences with the fluids of the body," all without the internal administration of drugs or medicines—and asked them whether they understood what it meant, and told them that I did not, I knew that this legislature at least was proof against the claims of osteopaths to have a board of State examiners of their own.

A few weeks ago a patient with the symptoms of a weak heart muscle, whom I had seen a few times, asked me whether I approved of his having

consulted, upon the advice of a friend, an osteopath. When I told him that I did not approve of being insulted by his asking me whether I consented to his consulting a quack he appeared crestfallen, and left. He reappeared after some little time to apologize, as he said, for having proposed a question I disliked to hear. My reply was: "Do not apologize to me, apologize to yourself. I can understand that there are ten thousand Catholics in New York who are cured of certain nervous diseases or disorders by kneeling before a Maria, or by praying to a saint; I can even appreciate that hysterical men and women are benefited by the confidence they have in what they are pleased to call Christian Science; but it takes a frame of what you call your mind and a mental darkness which are not intelligible to me to believe that any disease can be influenced by the anatomically and physically impossible feat of twisting a spinal bone this way or that way."

(To be continued.)

Original Communications.

HYPODERMATOCLYSIS.*

By W. PAGE McINTOSH, M. D.,

PORTLAND, ME.,

SURGEON, PUBLIC HEALTH AND MARINE HOSPITAL SERVICE.

In combating disease in the human organism there are three methods at our disposal; that is, there are three ways in which we may attempt to relieve our patients. First, by elimination; in this an effort is made to remove from the system the deleterious effects of disease. Second, the stimulation of the internal secretions, by this means increasing phagocytosis and the formation of antibodies. Third, the introduction of an antitoxic substance ready formed, into the circulation and endeavoring by a chemicobiological action to destroy either the germ or the toxine which it produces.

In calling your attention to the subject of hypodermatoclysis, I make no claim to have discovered something new, but only to have done considerable work in this line, and I think it a proceeding either not properly understood or greatly neglected.

A quotation from Huxley, which has been made to do much service of late, is quite appropriate here: "Let us sit down before *fact* as a little child, be prepared to give up every preconceived notion, and to humbly follow where Nature may lead." In order to go fully into the subject, I shall have to premise and call your memories back to the theories of protection and immunity. "This is essentially an age of progress and we find new and improved ways of approaching and solving problems. In this ad-

*Read before the Clinical Society, Portland, February 10, 1905.

vance we cannot fail to be forcibly impressed with the tendency of the age to discover and utilize more accurate and more practical methods of work; as medicine is placed more and more firmly upon a scientific basis, practical clinical methods of investigation with clinical studies of abnormal conditions and a scientific application of our knowledge in the treatment of disease take the place of theory.

"Practical clinical medicine is becoming the demand of the age. Speculative theories must give way in the presence of scientific realisms. Methods of greater accuracy and of more practical every day utility to the physician and surgeon must displace the earlier, uncertain, and less scientific methods of investigation and study" (1).

To properly study the practical application of a therapeutical method to the human economy, it is necessary to know the condition of the tissues to be affected both before and after the application—the modification or difference in these giving the result.

In the present state of our knowledge, it is somewhat more difficult to tell exactly how a remedy does good than it is to ascertain the fact that good has resulted from its use. Hypodermatoclysis no doubt acts to some extent by increasing the elimination of effete and toxic materials, but as it does not cause a large increase in the substance normally excreted by the kidneys, as proved by the normal or diminished amount of urea found in the urine after its use, it must accomplish its beneficent effect in some other way than by flushing out the system and diluting the toxins; there is no doubt a modicum of truth in this theory, but on the whole it is untenable.

The flushing out of the whole system and at the same time diluting and removing the toxins is a theory beautiful to contemplate in the abstract, and if it was only practicable we should have little trouble in curing our patients. An increase in the percentage of urea was expected after the use of saline solution, but in no case did this occur.

A study of the blood is of far more importance and gives us much valuable information. The theories of immunity while not heretofore applied to hypodermatoclysis seem to afford the most rational explanation of its beneficial action. There is a decided leucocytosis, and there is also a large increase in the number of erythrocytes produced by hypodermatoclysis. The leucocytosis has a direct bearing on the subject in the phagocytic theory of Metchnikoff and the erythrocytosis upon the oxygenation of the tissues; both profoundly affecting metabolism.

In an earlier part of this paper I spoke of calling to your minds these theories: I will now do so at

some length, using Sajous's (2) explanation (Sajous is quoted verbatim at times), the "Phagocytic theory of Metchnikoff is that the living cells seize upon and destroy the bacteria in the blood, the organisms that escape from one cell are seized upon by others, but if their multiplication is excessive they overpower the phagocytic leucocytes, and invade the blood stream. Various observers, Pfeiffer, Buchner, and others having demonstrated that the blood serum and other body fluids were likewise bactericidal; Metchnikoff ascribed this fact to the disintegration of the phagocytes, the properties of these cells being thus imparted to the serum. Bordet and other French observers showed this property to be due to two constituents of the plasma; the one (the specific immune body) circulates in the plasma according to Metchnikoff, and resists a temperature as high as 100° C. The other, cytase, thought to be derived from disintegrated phagocytes is destroyed at a temperature of 56° C. Cytase is considered by Metchnikoff as belonging to the category of trypsin. The view that the serum is endowed with bactericidal powers has been ably defended by Pfeiffer, Nuttall, and others. Buchner and Hankin isolated substances which they termed alexins, and to these bodies they ascribed the power to confer immunity. They were thought by Buchner to be derived from oxyphile leucocytes and kindred cells. Laschtschenka having isolated them from living leucocytes the bactericidal action was thought by Buchner to be due to a proteolytic enzyme similar to the ordinary digestive ferments. According to Gruber the bacteria cell walls were first made adhesive by the blood agglutinins and thus became vulnerable to the destructive action of the alexins.

"The side chain theory advanced by Ehrlich in 1897 aimed to harmonize the results so far reached in the study of natural and artificial immunity. This theory is not necessarily a complex one, and is based on recognized biological and chemical principles. The colonies of body cells differ from each other in their functional attributes. Nerve cells, muscle cells, gland cells, etc., each having a special affinity for certain drugs; the cerebrospinal cells having a special affinity for strychnine, the cardiac muscle cells for digitalis, the sweat and salivary gland cells for jaborandi.

"Now as toxins differ in no way from remedies in this particular, they are also specific owing to their affinities, toxin being also taken up by specific cells. This specific action represents the foundation of Ehrlich's theory. The theory itself is based upon the mechanism of cell nutrition in its mode of production of specific antitoxines, or bactericidal and antitoxic sera.

"The cellular protoplasm is very complex and Ehrlich assumes that each cell contains an active central nucleus and of groups of molecules or side chains; these extranuclear molecules he calls receptors. Since each of them has for its function the receiving of food molecules or haptophores (*ἀπρεψ*, to bring), a cell's nutrition is thus carried on through the affinity its *receptors* have for its haptophores.

"Unfortunately the receptors do not combine with nutritive substances only, but have an affinity for substances which may be their chemical analogues and which may include harmful bodies; thus a poison, toxine, or venom may contain the same elements and the same number of them as a nutrient molecule or haptophore, the atoms only being arranged differently (isomerism). Turpentine and oil of lemon each have the formula $C_{10}H_{16}$, though their properties are quite dissimilar. Ethyl formate and methyl acetate have the same molecular weight 74 and the formula $C_3H_6O_2$. It is possible then for a cell to take up any number of isomeric non-nutritive bodies, and when one of these happens to be toxic it is called a toxiphore. If the toxine is not sufficient to destroy the cell or inhibit its functions, the latter seeks to rid itself of the poison and to protect itself from any further aggression from this poison or its isomers. The toxic group of the haptophoric molecules attaches itself to the receptors and then reacts actively upon the cell proper; the receptors themselves being destroyed, the cell (in keeping with Weigert's theory of overproduction) not only reproduces them, but the process is so active that many more receptors are created than are required by the cell itself, and thus accumulate in the blood and lymph. These receptors still preserve their affinity for their specific haptophores, and their isomeric toxine; they therefore become cell protectors, capturing and holding the toxine before it reaches the cell."

Haffkine's prophylactic is a good illustration of this action, a toxine being introduced, the system forms its own antitoxine. I think it is probable that the saline solution stimulates the formation of receptors and thus protects. You know it is said by very good observers that the arrow poison used by the South Sea Islanders and other savage tribes is not effective against people who partake freely of salt in their food, although deadly to other animals. (8) Lambinet, quoted by Ashford and King, in their *Report of Anæmia in Puerto Rico*, found that immersion in a two per cent. solution of bichloride of mercury, or a three per cent. solution of lysol for one hour would not kill ova of the *Uncinaria Americana*, while a strong solution of salt was fatal. This is of course due to hyroscopic action and does not apply here. Again, Metchinkoff states

(and this is probably the gist of the whole matter) that his tryptic cytase acts only in the presence of salts, and that when relieved of its salts by dialysis the serum loses its hæmolytic power, but when the salts are restored to it this reappears. In pneumonia the chlorides disappear from the urine and accumulate in the lungs, as shown by Beale a number of years ago, their action in the lungs being no doubt to increase the efficiency of the protective action of the pulmonary fluids (3). Again the presence of proteolytic enzymes in the serum has been recently demonstrated by Delezenne and Pozerski, and the results confirmed by Hedin. The latter investigator states that the serum of the ox contains a weak proteolytic enzyme which acts in an *alkaline* medium. The origin of this enzyme we have traced as well as the increased alkalinity and the supply of salts necessary to render serum hæmolytic.

"The three prominent theories of immunity have several features in common, one of these is that the destruction of the bacteria in the blood serum is ascribable to a substance which Metchinkoff calls cytase. Buchner calls it alexin, and Ehrlich complement. Another is that the bactericidal body is derived from the leucocytes. Metchnikoff thinks it comes from the phagocytes. Buchner traced it to oxophylic leucocytes, while Ehrlich is inclined to believe that his bacteriolysins are derived from these cells. All three theories concur in recognizing that the blood destroys pathogenic organisms by means of a digestive (ferment) substance, and that this substance is derived from the white blood cells. This proteolytic ferment is believed by Buchner, Hankin, and Sajous to be supplied to the leucocytes by the ductless glands."

The sodium chloride solution itself probably has the action of a digestive ferment in the blood. A. Robin (4) announces that "a solution of a metal, in a proportion of .0009 to .0002 gramme to the cubic centimetre, has a most remarkable action when injected subcutaneously. It displays a physiological action, like that of a true ferment, out of all proportion to the minute amount of the metal employed. . . . The injection is followed by leucocytosis. Fourteen cases of pneumonia were treated and the crisis was hastened in each case, the temperature dropping to normal before the seventh day. . . . The metal ferments evidently stimulate the reaction of the organism, reinforcing the natural resisting powers and superposing on the vital and personal reactions a parallel activity revealed by the more rapid disappearance of the correlative symptoms of the infection. . . . The therapeutical use of the metal ferments is an attempt to apply in the clinic the new data furnished by physics and chemistry in the last few years in regard to radioactivity,

ionization, and atomic energy, diastases, zymases, minutely divided metals and catalytic phenomena." At this time when we are seeking antitoxic sera for all infectious diseases, saline solution is extremely useful and should be used in all cases when a specific antitoxine is not obtainable, as it acts much in the same way, only its field of action is greater and its applicability wider.

From experiments and observations which I have been able to make I can prove, I think, that the use of saline solution by hypodermatoclysis causes a decided increase in both the erythrocytes and the leucocytes. It is also probable, but not proved, except by the leucocytosis, that it stimulates the ductless glands to increased activity.

The following cases were undertaken to ascertain, if possible, the mode of action of hypodermatoclysis; the mode of procedure was this: A patient who was convalescent or suffering from some slight ailment was selected. The urine for twenty-four hours was saved and analyzed, on the day before the hypodermatoclysis was used, the twenty-four hours reaching up to the time of injection. Just before the saline solution was used, a count of the leucocytes was made and a hæmotocritic estimate made of the red cells. In some cases these were also counted. In a few cases an estimate of the hæmoglobin was made. Care was taken to make the counts and estimates on alternate days at the same hour, late in the afternoon, so that no meal had been partaken of for some five hours. From one thousand to fifteen hundred cubic centimetres of a nine tenths of one per cent. saline solution was injected and the leucocytic count and hæmotocritic estimates were made again in twenty-four hours; this was done in order to make a correct estimate of effects of infusion; an immediate count would have shown a lessening of both white and red cells, owing to greater fluidity of blood. The urinary analyses were made with particular reference to the chlorides and urates.

No differential count of the various forms of leucocytes was undertaken, as I regard them as transitional; belonging to the same class, presenting but slight differences in different situations:

CASE A.

	Erythrocytes.	Leucocytes.
	c.mm.	c.mm.
Before hypodermatoclysis.....	2,700,000	6,960
After hypodermatoclysis.....	4,500,000	11,800
Gain.....	1,800,000	4,840

A gain of 66 per cent. in red cells and of 69.5 per cent. of leucocytes.

CASE B.

	Erythrocytes.	Leucocytes.
	c.mm.	c.mm.
Before hypodermatoclysis.....	6,000,000	28,640
After hypodermatoclysis.....	5,000,000	48,000
Loss.....	1,000,000	Gain.....19,360

A loss of 16 per cent. in red cells, but a gain of 67.6 per cent. in leucocytes.

CASE C.

	Erythrocytes.	Leucocytes.
	c.mm.	c.mm.
Before hypodermatoclysis.....	3,700,000	8,600
After hypodermatoclysis.....	4,300,000	8,732
Gain.....	600,000	132

The percentage of gain here in reds was very good, amounting to 16 per cent.; the percentage of leucocytes was not materially increased, being only a little over 1 per cent.

CASE D.

	Erythrocytes.	Leucocytes.
	c.mm.	c.mm.
Before hypodermatoclysis.....	4,700,000	5,328
After hypodermatoclysis.....	4,900,000	6,397
Gain.....	200,000	1,709

The percentage of gain in red cells about 4 per cent.; in leucocytes over 30 per cent.

CASE E.

(Fleischel's)

	Erythrocytes.	Hæmoglobin.	Leucocytes.
	c.mm.	Per cent.	c.mm.
Before hypodermatoclysis.....	4,700,000	75	4,000
After hypodermatoclysis.....	4,900,000	104	8,680
Gain.....	200,000	29	4,680

A gain of a little over 4 per cent. in red cells. The leucocytes are more than doubled, being 117 per cent. gain. Hæmoglobin increased 29 per cent.

CASE F.

(Fleischel's)

	Erythrocytes.	Hæmoglobin.	Leucocytes.
	c.mm.	Per cent.	c.mm.
Before hypodermatoclysis.....	4,000,000	75	7,320
After hypodermatoclysis.....	4,200,000	80	12,928
Gain.....	200,000	5	5,608

A gain of 5 per cent. in red cells; 76.6 per cent. gain in leucocytes and 5 per cent. gain in hæmoglobin.

URINE.

CASE A.

Quantity in 24 hours.	Specific gravity.	Urea.		Chlorides.	
		Per cent.	Grains.	Per cent.	Grains.
Before hypodermatoclysis.....	1.015	833	2.7	123	0.4
After hypodermatoclysis.....	1.015	772	2.35	205	0.625

A marked increase in the chlorides, but a diminution in the quantity of urea excreted.

CASE B.

Quantity in 24 hours.	Specific gravity.	Urea.		Chlorides.	
		Per cent.	Grains.	Per cent.	Grains.
Before hypodermatoclysis.....	1.028	787	5.1	15.43	0.1
After hypodermatoclysis.....	1.014	752	2.2	162	1.05

Again an increase of chlorides and a decrease in urea. Quantity of urine increased greatly.

CASE C.

Quantity in 24 hours.	Specific gravity.	Urea.		Chlorides.	
		Per cent.	Grains.	Per cent.	Grains.
Before hypodermatoclysis.....	1.026	228	2.8	106	1.3
After hypodermatoclysis.....	1.028	207	2.4	123	1.425

Another increase of chlorides and a decrease of urea. Slight increase in quantity of urine.

CASE D.

Quantity in 24 hours.	Specific gravity.	Urea.		Chlorides.	
		Per cent.	Grains.	Per cent.	Grains.
Before hypodermatoclysis.....	1.018	262	2	68	0.52
After hypodermatoclysis.....	1.011	250	1.1	131	0.575

Urea again decreased, chlorides increased, as is quantity of urine passed.

	Quantity in 24 hours. c.c.	CASE E.				
		Specific gravity.	Urea.		Chlorides.	
			Grains.	Per cent.	Grains.	Per cent.
Before hypodermatoclysis	925	1.026	314	2.2	164	1.15
After hypodermatoclysis	1,660	1.016	461	1.8	220	0.86

Quantity of urine passed nearly doubled, urea diminished from 2.2 per cent. to 1.8 per cent., though, owing to increase in urinary secretion, the actual quantity of urea increased.

	Quantity in 24 hours. c.c.	CASE F.				
		Specific gravity.	Urea.		Chlorides.	
			Grains.	Per cent.	Grains.	Per cent.
Before hypodermatoclysis	870	1.019	282	2.1	148	1.1
After hypodermatoclysis	750	1.019	208	1.8	122	1.05

A decrease in percentage of both urea and chlorides.

The strength of the salt solution I have generally used was the so called normal physiological, which is 0.6 of 1 per cent. Recently I have been using a 0.9 of 1 per cent. solution, as according to Mathews (5) (*Annals of Surgery*, August, 1904), which strength of solution has the same freezing temperature as the blood. "If the solution is too concentrated the red cells shrink; if too dilute they first swell and later part with their hæmoglobin. The question of shrinking or swelling of the cells is determined by the osmotic effect and not by the chemical composition of the fluid. The osmotic behavior of blood plasma and saline solution is shown by a method based on the fact that two solutions having the same freezing point have the same osmotic pressure. Hemotocrit determination of the salt solution in which red cells neither shrink nor swell gives about 0.9 per cent. This then seems to be about the proper strength to use."

The physiological effect of hypodermatoclysis (probably) is to stimulate the ductless glands, causing an increase of the internal secretions. Certainly an increase of the leucocytes with a consequent increase of the enzyme, cytase, or alexin, increased phagocytosis, with an increase of Ehrlich's receptors; a very decided addition to the salts of the serum with an increase or restoration of its hæmolytic power; an increase in the alkalinity of the serum which, as has been shown, adds greatly to its bactericidal properties. The clinical effects of hypodermatoclysis are to raise the blood pressure, and to strengthen and regulate the pulse. The increase of the erythrocytes enables the blood to carry more oxygen, and the respirations are deeper and less rapid; the blood and tissues are more thoroughly oxygenated; the skin becomes moist (and warm if cold before). Diuresis is increased; the mind becomes clearer, sleep is promoted, the appetite is improved, the patient is encouraged, and there is a feeling of well being.

The following cases will illustrate the good effects of hypodermatoclysis:

CASE I.—Hæmorrhage and Shock.—This man was brought to the Marine Hospital at Louisville, Ky., suffering from the following injuries: The right leg had been torn off at the knee by being caught in the hawser line of a steamer, as she was being tied up. The line had become entwined around the man's leg and as the vessel swung around, the leg was first lacerated and fractured and then pulled off. Both bones of the left leg were also fractured. The shock was intense; there had been great loss of blood, the man being almost exsanguinated; hypodermatoclysis was begun at once, hot salt solution being used, and a rapid amputation at the middle third of the thigh was made. The man had bled so much before reaching the hospital, that there was no oozing from the stump; not even a jet from the femoral when pressure above was removed. The vessels could only be tied by knowing their relations; this all occupied about three quarters of an hour and during this time 1,000 c.c. of saline solution had been absorbed and the pulse at the wrist was perceptible. No one present thought the man could live, but the hypodermatoclysis was kept up and 3,000 c.c. was injected and absorbed in the next eight hours; that is, up to 9 a. m. At this time the patient was conscious, the pulse fast, but regular; during the day 2,000 c.c. more of the solution was used, the patient was given beef juice, wine, etc. This man recovered and when last I saw him was a living monument on a wooden pedestal, a pillar of salt, as it were, proclaiming the efficacy of hypodermatoclysis.

CASE II.—La grippe. Double pneumonia. White, male, age 31 years, place of nativity, Maine. Entered the hospital suffering from influenza. In a few days he developed pneumonia in left lung. The clinical notes state: Pronounced dullness at apex of left lung, both behind and in front, with crepitant râles in left side posteriorly; also considerable pain in left side; mucous and moist râles throughout chest; hyperresonance on right side; temperature, 40° C.; pulse weak and irregular; stimulants and creosotal were used. Two days later (November 21st) the right lung noted as being affected like the left, percussion showing marked dullness on both sides with crepitant and moist râles throughout chest. Pulse weak and irregular; missing every seventh beat, gaseous and easily compressible. No effusion in pericardium. Strychnine and nitroglycerin every four hours. November 22nd, patient extremely weak, pulse irregular, missing one in every five beats and wavering. Respirations, 60 a minute, temperature subnormal 35.8° C., about 96.5° F. Skin cyanosed and bathed in cold perspiration, pupils dilated, man seemed to be dying; 1,500 c.c. hot saline solution injected under the skin of abdomen (hypodermatoclysis), patient reacted, skin became warm, pulse stronger and more regular, missing one in twenty. Stimulants continued, strychnine, digitalis, etc. November 23rd, man again in collapse, temperature 36° C., pulse thready, 120 a minute; hypodermatoclysis again resorted to, 1,500 c.c. of solution being used; patient reacted slowly, slept some through the night, first good sleep he has had for several days. From this time patient improved and made a good recovery.

There was no swelling or febrile reaction in any

of the cases. One case, of rheumatism, in which there was some swelling at the site of puncture, with a rise in temperature, was thrown out.

In a number of cases of enteric fever when the patient was extremely ill, with a low muttering delirium, subsultus tendinum, dry skin, dry cracked tongue, etc., I have found that the use of from 1,000 to 1,500 c.c. of saline solution by hypodermatoclysis produced a refreshing sleep, with subsidence of delirium, and a moist skin and tongue. It is in fact in just these cases where we seem to have done all we can and nature appears to be giving up the struggle that hypodermatoclysis comes in and often saves life. With this treatment there is a lessening of mortality, a more satisfactory convalescence, the patient is made comfortable, and there is less thirst with an increase in the amount of urine secreted.

According to Clark and Norris (6) the intraperitoneal infusion of saline solution minimizes the dangers of pyogenic infection. I seldom make a laparotomy without infusing into the abdominal cavity a quantity of saline solution just before tying the last stitch.

(7) Heidenburg (*Roussky Vrach, N. Y. Med. Jl. and Phila. Med. Jl.*, April 23, 1904) calls attention to the uses of saline solutions subcutaneously in the treatment of the insane. The results of this treatment consist in calming the excitable patients, promoting sleep and appetite. It is indicated in mental diseases of infectious and autotoxic origin. As a rule the insane bear these infusions well and do not object to them.

Indications: Personally I can speak of hypodermatoclysis only in hæmorrhage, shock, uræmia, puerperal eclampsia, typhoid fever, pneumonia, and anæmia; in these cases it often saves life and always does good.

In poisoning from illuminating gas, ether, and opium this procedure is highly recommended, as it dilutes the poison and favors elimination. In diseases attended with great loss of body fluids, such as cholera, cholera infantum, enterocolitis, the remedy is of great service. It is also one of our best remedies in septicæmia. On account of the leucocytosis it produces, saline solution should be used in puerperal sepsis. As before stated it is excellent in rheumatism and infectious diseases generally. The remedy is recommended in diabetic coma, restoring consciousness and prolonging life.

Hypodermatoclysis is not a remedy for everything. To the surgeon I would say, use it always after hæmorrhage, in shock, and often to prevent shock; he will find it his *best* friend; to the obstetrician in eclampsia, and after post partum hæmorrhage, provided the hæmorrhage is well under control. To the physician, I say use it in

anæmia, enteric fever, and pneumonia; in all of these it will help him, and in the last two mentioned will often save a precious life when all else has failed.

Since writing above I have had excellent results in several cases of rheumatism, both muscular and articular, by use of hypodermatoclysis; in one case the pains disappeared as if by magic.

I am indebted to Pharmacist Charles W. Stephenson for making the urinary analyses, and to Dr. F. Leo Quigley for making the blood counts.

Howard University, of Washington, D. C., graduated the following in medicine on May 25th:

Thomas Austin, Milton H. Auter, York W. Bailey, Allen Everett Beatty, John Wesley Salter Beckett, Norman Hamilton Brewster, David Thomas Cardwell, James Cleyborne Carper, Wallace B. Christian, Frank Frederick Davis, Edward V. Fitzgerald, S. Bernard Hughes, John C. Hunter, Mary Anna Israel, James F. Johnson, A. St. Clair Jones, Malchiah Maxwell Lucas, Hamilton St. Clair Martin, William Jackson Parks, Charles Sumner Taylor, and William James Thompkins.

American Chemical Society.—The thirty-second annual meeting of this society will be held at Buffalo, June 22nd to 24th, in the rooms of the Buffalo Academy of Natural Sciences. Papers will be heard as follows:

Address of Welcome, by Mr. Herbert P. Bissell; Response, by Mr. Francis P. Venable; The Classification of the Carbon Compounds, by Mr. Marston T. Bogert; Some Recent Advances in Physiological Chemistry, by Mr. John H. Long; The Electro-chemical Industries of Niagara Falls, by Mr. Francis A. J. Fitzgerald; Tellurium, by Mr. Victor Lenker. Reports from universities and colleges on research work.

Baltimore University School of Medicine.—The annual commencement of the Baltimore University School of Medicine took place on May 3rd. Appended is a list of the graduates:

Max D. Bier, of New Jersey; E. E. Brophy, of New York; W. A. Dietrich, of New Jersey; Edward W. Gardner, of New York; M. A. Godfrey, of Massachusetts; Thomas I. Kealy, of Pennsylvania; John C. Kibler, of Pennsylvania; Daniel H. Leddy, of Rhode Island; A. D. Lindemann, of New York; B. F. Matheny, of West Virginia; S. W. Riddell, of West Virginia; D. E. Ritter, of West Virginia; Victor I. Shapiro, of Massachusetts; A. J. Thome, of Pennsylvania; Z. A. Thompson, of West Virginia; J. W. Webb, of West Virginia.

OBSERVATIONS ON THE DIAGNOSIS AND TREATMENT OF HERPES ZOSTER.*

By DAISY M. ORLEMAN ROBINSON, M. S., M. D.,

NEW YORK,

*CLINICAL ASSISTANT IN DERMATOLOGY, NEW YORK POLYCLINIC MEDICAL SCHOOL AND HOSPITAL.

It is my desire to bring to your attention the efficacy of certain therapeutical measures which in my experience have been of benefit in the treatment of herpes zoster, and I hope to be able to convince you of the value to the patient in all cases of an early diagnosis and of immediate active treatment. A study of the literature of the subject will show that the treatment recommended consists of internal remedies for the pain and local applications for the eruption. In my opinion the principles guiding the administration of internal remedies ought to be based especially upon the character of the disease, although remedies for the relief of pain and local treatment for the eruption should be employed.

In order to form a correct diagnosis one should necessarily be familiar with the symptoms of the disease as it usually occurs and likewise with other symptoms showing unusual characters. The symptoms of this disease vary in accordance with the severity of the affection, the location of the eruption, and the aetiology of the disease.

Herpes zoster may be defined in broad terms as an acute inflammatory disease of a definite duration and course, characterized by the presence upon the skin of lesions which when fully developed are vesicular in character with a tendency to coalesce and form bullæ. The lesions group to form patches of various sizes and the lesions of a single patch are usually of about the same age, although they may differ in age from the lesions of other patches or even from the other groups of the same patch. The eruption is almost always unilateral and situated on a definite anatomical area corresponding generally to the region supplied by one of the cranial or spinal nerves.

The region ordinarily affected is the dorsopectoral in which the disease involves the intercostal nerves. The lesions commence as papules and become vesicles when fully developed. An erythematous condition of the region occupied by the fully developed lesions usually precedes the appearance of the characteristic zoster eruption. This erythema is limited usually to the region supplied by the special nerve or nerves affected and extends generally some distance beyond the area of the eruption, and again it sometimes appears diffusely over large areas of the body where

the characteristic vesicular lesions do not form. This early erythema may be absent or possibly very slight and may be sharply limited to the individual areas corresponding to those occupied later by the separate groups of vesicles. It may be present only in a portion of the affected nerve region, as some of the groups of vesicles may arise upon apparently a normal skin, others upon a part showing a mottled reddish appearance and others upon a well marked diffuse erythematous area. This erythema diminishes markedly or entirely upon the appearance of the vesicles, although an erythema in connection with the individual vesicle formation is always present, each vesicle having an erythematous base of greater or lesser extent.

Red miliary papules quickly appear upon this erythematous base; these generally develop within a few hours to twenty-four or more into vesicles that vary in size from a pin head to a pea. The lesions are arranged into groups of different sizes. The groups form patches of greater or less size which are irregularly distributed over the affected area. The lesions of a single group vary in number from two, three, or more to perhaps ten, fifteen, twenty, or more, and the groups are separated from each other by normal skin. Isolated lesions are found frequently some distance from the groups forming the large or small patches. Some of the lesions in a formed group may not develop into vesicles, but abort at the papular stage. The lesions, however, have a tendency to increase in size and become fully developed vesicles that may coalesce to form larger or smaller bullæ. Such is the case especially with the lesions in the central part of a group.

These vesicles and bullæ show but few changes in character for several days. The clear serous contents then become turbid and finally puriform and as a rule dry into yellowish brown crusts in about a week to ten days after their appearance, leaving a dark red or pigmented spot which may disappear later. There are many cases in which cicatrices or pigmentation remain permanently, but this is infrequent when the disease is located in the pectoral region. The eruption lasts from one to two, or even three weeks, usually running its natural course in about two weeks, which course may be curtailed and also modified in severity by certain therapeutical measures.

The above summary description of the eruption represents a classical case of zoster pectoralis as regards the objective characters. There are, however, many variations; thus, there are cases in which only an erythematous stage with small papule formation occurs *without* vesicle formation and in which the life duration of the lesions is lim-

*Read before the Medical Society of the County of Westchester, N. Y., March 21, 1905.

ited to a few days. Cases have been reported where no eruption has occurred, not even an erythema, the diagnosis having been made on the location and character of the pain.

Hæmorrhage into some of the vesicles of the lesions may also occur and brownish crusts form upon drying of the contents. This form occurs oftener in elderly persons or in those of lowered nutrition or with a dyscrasic condition. The following is the history of a case at present under my care:

A. B., aged 65 years, occupation, laborer. The patient is apparently in good physical condition and without any record of previous serious illness. The eruption is an example of zoster lumbosacralis and consists of a large number of patches of various sizes, the largest one containing fully one hundred lesions. The lesions vary in size from a pin head to a pea and only a few of the larger lesions have coalesced to form bullæ. A large number of the lesions did not continue to the development of well formed vesicles, but seemed to abort in an early vesicular stage, the contents being serosanguineous in character imparting to the lesions a dark red color. Some of the lesions contained very little blood and others had clear serous contents. The case was one of zoster with hæmorrhage into some of the lesions and was not therefore one of pure hæmorrhagic zoster. Brownish crusts covered the lesions which crusts were subsequently thrown off in the usual manner. The entire cutaneous area occupied by the lesions showed a hæmorrhagic exudation into the tissue giving the surface a dark color.

Previous to the appearance of the eruption there was a numb feeling of the part—anæsthesia—as the patient could prick himself with a needle without causing any pain. He had also anorexia, fever, and sleeplessness. The numbness disappeared three days later and one day before the appearance of the eruption. It was followed by sharp, lancinating pains which continued in varying degrees for several days until he was treated for this condition. The case is still under my care, hence at the present time a complete history of it cannot be given nor a statement made whether there will be a recurrence of the pain.

The microbic origin of the disease may be assumed from the history of this case as evidenced in the (1) prodromal symptoms, (2) definite course and, more particularly, (3) hæmorrhagic character of the exudation in a large number of the lesions, while some of the other lesions contained clear serum.

There is a form called zoster hæmorrhagicus in which the hæmorrhagic vesicle is the type. The vesicles usually burst in this form and an ulceration occurs with destruction of tissue, as there is always more or less destruction of the cutis papillæ. After perhaps a period of two or three months the part heals by granulation or cicatrization.

This hæmorrhagic form seems to occur more frequently in zoster occupying some portion of the head region, especially zoster ophthalmicus.

A mixed infection occurs in some cases from pyogenic organisms, resulting indirectly from scratching or other injury to the lesions, and an impetiginous-like condition arises which may make the original zoster lesions difficult of recognition.

Cases of bilateral zoster occur exceptionally either on corresponding regions or on those quite distinct from each other.

The eruption is preceded in the majority of cases by pain in the region where the cutaneous lesions appear. This pain varies from a dull aching or throbbing to a sharp lancinating, and is often burning or itching in character, accompanied at times by paroxysms most severe at night. It may be so intense as to interfere with the use of the muscles of the part and when situated in the thoracic region may cause the physician to suspect an attack of pleuritis. It may even affect neighboring nerves outside of the diseased cutaneous area and may be quite disproportionate in intensity to the extent of the eruption. Sometimes pain may be absent, especially in children, but, as already mentioned, it is usually present in a greater or less degree in nearly all cases.

This difference in the amount of pain is due possibly to a difference in the intensity of the inflammatory process at the seat of the cutaneous lesions, or to the injuring action of this process on the spinal ganglia. It might also be attributable, in the case of children, to a difference in the histological structures of the parts at this period of life, or to a lessened virulence of the organisms and their toxins in consequence of which there is less injury to the tissues or to both.

As an example of long continued hypersensitiveness and even pain I will cite a case I saw some weeks ago of a woman aged 45 years, who had had a severe attack of zoster occipitocollaris, one year ago. As reported to me, the eruption consisted of patches that were both numerous and large. The lesions were well developed, forming large bullæ in most of the patches and lasting about twenty days before drying up. This patient informed me that she had never been entirely free of pain, tenderness, itching, or discomfort in the affected region since the time of the eruption, although there were intervening periods in which the condition was apparently almost normal.

I have knowledge of one case in which severe neuralgia lasted over twenty years until the death of the patient from cancer of the stomach. This patient was obliged to resort to morphine for the relief of the pain and became eventually addicted to the morphine habit.

There is often a painful swelling of the corresponding lymphatic ganglia occurring at the same time, or even preceding the cutaneous eruption. This primary or secondary lymphadenitis and the lymphangitis which sometimes follow suppuration of the vesicles may be the cause of painful phenomena.

Other premonitory symptoms, such as fever, malaise, headache, and digestive disturbances are quite frequent and tend to show an incubation period and the infectious nature of the disease. These prodromal symptoms may persist several days after the eruption appears, but they usually disappear rapidly at that period. The pain, however, often continues much longer and, as previously stated, when persisting after the eruption it is obstinate to treatment and has been known to last months or even years, rendering life more or less miserable. These severe and persistent pains seem more likely to occur in aged or neurotic individuals, and may remain absent for weeks at a time and reappear with greater or lesser severity.¹ I am satisfied that the importance of endeavoring to prevent these pains is often not sufficiently considered when a case of zoster first comes under our professional care.

There may occur, after the healing of zoster, a muscular paralysis, although quite rare, which is localized to the region previously occupied by the eruption. In such cases there are presented the ordinary symptoms that are observed in muscular paralysis of children as regards muscular atrophy and the reaction of degeneration. Hardy has reported one case of fatal ascending myelitis following a thoracic zoster. Facial paralysis in connection with cervical zoster is the most frequently observed form of paralysis. Hutchinson has reported one case where there was a total paralysis of the motor oculi communis nerve with ptosis and mydriasis occurring six days after the eruption.

I will now pass around a number of illustrations of pectoral zoster, as it usually appears in this region, and which form I have especially attempted to describe. You will note in these illustrations: the region of the body occupied by the eruption, the number of groups of lesions, the large number of lesions in a group, the marked similarity in age of the lesions of a single group, the frequent difference in ages in the lesions of the different groups, the inflamed base or seat of

the lesions, and the vesicular and bullous character of the lesions; also the puriform appearance of many of the vesicles and bullæ, especially in the central part of the patches.

As showing variation in the number of groups, I will report a case lately under my observation:

Case of a girl, 10 years of age, who complained of pain over the spine, first dorsal region, followed by three small areas of inflammation, upon which well marked lesions appeared the following day. These inflamed areas appeared, one opposite the first dorsal near the spine, a second near the right mamilla, and a third between the mamilla and the anterior median line. The temperature on the day of the first appearance of the erythematous patches was 100°, and on the following day (the time of commencing formation of vesicle lesions) was 99.7°.

Blood examination showed a condition of secondary anæmia. There was no diminution or increase in the number of leucocytes or of red corpuscles.

The lymphatic glands of the axilla of the same side were inflamed, tender, and much enlarged, and there was considerable pain on the right side of the thorax in the area afterwards occupied by the eruption.

Following is a description of the eruption as it appeared in the three areas occupied by the lesions: Two papular lesions situated closely together half an inch from the median line and opposite the first dorsal vertebra, both pin point in size, slightly elevated, reddish in color, the redness disappearing on pressure and returning quickly with a feeling of resistance in the part, showing exudation into the tissues. Both lesions were exactly of the same age and were situated upon a reddish base. One inch below and very slightly further from the spine than the first lesion there was a small patch, one third of an inch in horizontal and one sixth of an inch in perpendicular diameter, sharply limited, elevated, reddish in color, the redness disappearing upon pressure. Observing the spot immediately after pressure showed the apparently erythematous patch to be composed of three individual lesions, little papulovesicles, pin point in size.

From the lower angle of the scapula on an area extending from the lower border of the scapula to the ninth rib and from one and one half inches to the right of the posterior median line, and one and one half inches to the outer side of the lowest point of the scapula, there was a patch formed by five groups of lesions. The largest group was situated near the spinal cord and was one and one half inches in perpendicular diameter and one and one quarter inches in transverse diameter, and was composed of over thirty lesions; these lesions, forming a single large group, were also arranged to form smaller groups.

The lesions of the groups varied in size from that of a small pin head to four or five times that size, but were evidently of the same age and character, varying *only* in size. They were sharply limited, elevated, reddish in color, and in a vesicopapular stage, slightly more papular than vesi-

¹As an example of zoster coupled with severe persistent neuralgic pain in aged persons, I will mention a case in a man, aged seventy-five years, who one year ago had zoster dorsospectoralis of the usual duration as regards the eruption. This patient has ever since suffered from intense and continuous pains to the present time, experiencing exacerbations in damp weather. He did not receive any treatment during the eruptive period of the disease. Numerous other similar cases might be cited.

cular. Two of the groups at the lower border of the scapula, consisting of about one dozen lesions in each group, presented similar characters as regards color, size, etc., to the lesions just described. One group, which was lowest and nearest to the axillary line, contained one lesion like those already described, and very small pin point sized lesions, evidently of the abortive type, that is, lesions that will not develop beyond the papular stage. The fifth group of lesions was situated directly below the first described and consisted of a large pea size patch which, upon pressure, was seen to be composed of three small papulovesicles, with the skin between them reddened, so as to cause the little group of lesions to appear as one large lesion.

There were no lesions from the seat of these now described until the mammary region was reached. One half of an inch above and to the inner side of the right mamilla was a patch, triangular in shape, one inch in length, from apex to base, and one half an inch in diameter at the base, which base lay toward the shoulder and the apex was directed downward and inward. It was composed of three separate groups of lesions, the oldest of which, situated in the angle of the base nearest the shoulder, was large, pea-sized, elevated, with a reddish periphery, the redness disappearing partly upon pressure.

The central portion was covered by a honey-like crust, beneath which was clear serum that upon pressure easily flowed from beneath the crust. There was a triangular shaped group in the other angle of the base forming a reddish patch one half inch in its long diameter by one fifth of an inch in breadth at the base. It appeared as an acute inflammatory lesion, elevated, and showing an early papulovesicle formation along the central part of the ridge. With the magnifying glass it was seen to be composed of six little papulovesicles, each pin head in size, having a reddish periphery and a slightly paler centre.

The third group, forming the apex of the triangle, was composed of about eight commencing vesicles, five of which were united so that the individual lesions could be recognized only by means of a magnifying glass. Two at the very apex were isolated and were not quite as far in development as the others, being very slightly elevated, pale reddish in color, and showing no signs of vesicle formation. The right mamilla was abnormally red in color, as shown by comparison with the pale color of the left mamilla.

A small group, one inch to the inner side of the mamilla, and on a level with it was composed of three lesions, each isolated, the intervening skin being very slightly erythematous. Each lesion was pin head in size, elevated, with a reddish periphery and the central part was vesicular in character.

One half way between this group and the median line, on a level with the lower border of the ensiform cartilage and extending to one half an inch from the anterior median line, was a patch more or less circular in shape and about one inch in diameter, which was composed of six individ-

ual groups of lesions of varying sizes. Two of the larger groups were composed of ten to fifteen lesions, respectively, showing vesicle formation with a little yellowish crusting upon some of them, while others did not even show a well developed papule formation and were, doubtless, abortive lesions. The other groups were composed of lesions, from three to four to one half a dozen papulovesicles, all of which were of the same age. In none of the patches present on the body, except in the small patch near the mamilla, had lesions coalesced, nor were bullæ present.

The patient was placed under treatment to be described later. In six days the lesions had all dried up, the papules present not proceeding to vesicle formation; that is, the disease was apparently aborted. The neuralgic pains disappeared completely on the fourth day of the eruption. A slight tenderness of the affected axillary lymphatic glands continued a few days longer.

I will now describe a case lately under my care showing an unusually small number of patches and few lesions in a patch, with some of the lesions of very slight development:

A case of zoster dorsoabdominalis, lasting about ten days, and accompanied with considerable neuralgic pain in the region affected. There were three small patches, one near the spine, a second slightly anterior to the axillary line, and a third near the anterior median line, the last represented by an erythematous patch with two very small papules.

The disease started in the patch situated near the axillary line by the formation of one small papule upon a slightly erythematous base, accompanied by considerable pain. Two days later a half a dozen new papules appeared, arranged as a group upon a marked erythematous base of about one and one half inch in diameter. These became vesicular, some coalesced to form bullæ which lasted one week, then dried up, forming crusts which gradually disappeared, leaving a reddish surface. The patch near the spine consisted of only a few lesions which aborted before becoming well developed vesicles. The two very small papules near the anterior median line did not develop into vesicles, but dried up after an existence of two days.

A feeling of lassitude preceded the outbreak of the eruption and upon its appearance the temperature arose to 101°, but in forty-eight hours became normal. The neuralgic pain and tenderness of the abdominal muscles continued with considerable severity for two weeks.

I report this case on account of the considerable general disturbance of the system in connection with a very slight cutaneous eruption, which shows that the injury to the sensory nerves is not necessarily in proportion to the number of the cutaneous lesions or to the extent of the patches formed by them.

Lesions do not always form upon an erythematous area. Recently, in a marked case of zos-

ter lumbosacralis, in some of the patches and notably a large patch on the external surface over the knee, consisting of about forty lesions, the lesions were isolated and situated upon otherwise apparently normal skin. Smaller patches on the extensor surface showed also a similar condition. Two patches on the inner surface of the thigh had a general erythematous base.

Zoster may appear on any part of the body, although about sixty per cent. of the cases reported have appeared on the trunk. Zoster of the extremities is comparatively rare. Regarding other varieties the clinical picture and symptoms are the same in all of them—the only difference being in the location and severity of the disease in different cases, the most severe being those of the head region.

Illustrations which I will pass around show right zoster sacrocralis; right internal brachial zoster; one case in which it is to be noted that the lesions extended to the palm of the hand, and even to the finger tips, and another case in which the lesions are situated on the extensor surface of the arm and dorsal surface of the hand, including the fingers. I also show you illustrations of zoster of the head, and it will be observed how severe the disease may be in these cases.

There is a subvariety of facial zoster, zoster ophthalmicus, to which it may be advisable to devote a short time, owing to the serious character of the eruption in this region. This form occurs in nineteen out of twenty cases of cephalic zoster. The region supplied by the supraorbital and frontal nerves is often the only part affected. The cutaneous lesions occupy the forehead and anterior half of the scalp.

The eruption in ophthalmic zoster occupies especially the inner half of the upper eyelid. If it is situated on the external commissure the lacrimal nerve is affected. The upper eyelids are very oedematous; usually there are conjunctival injection and photophobia and the supraorbital neuralgia is apt to be severe. The injury to the eye structures may be quite serious; there may be iritis, keratitis, or even panophthalmitis with destruction of the eyeball and possibly pyæmia with a fatal termination. Ophthalmic zoster is therefore the most serious of all the forms of the disease. The Gasserian ganglion is almost always tumefied, and there may even be hæmorrhagic exudation into its structure as appears in some specimens which I have in my possession. Cases have been reported where paralysis of the muscle of the eye with ptosis, strabismus, and disturbances of accommodation have occurred. The frequency of ocular complications makes an early prognosis of ophthalmic zoster one of reserve.

When the nose is affected the nasal nerve takes part in the process. The law of Hutchinson that the eye is affected if the nasal nerve is affected has been accepted as a general law, although some exceptions to it have been observed.

DIAGNOSIS.

The prodromal symptoms, the unilateral location, the special anatomical distribution corresponding to the nerve distribution of one or more nerves, the grouped arrangement of the lesions, the rapid development of the lesions into vesicles, which are not acuminated and do not readily rupture, the tendency to coalescence, of some of the lesions to form bullæ, the marked similarity in age of the lesions composing a single group or even a patch, the frequent difference in age of the lesions of different patches and groups, the adenopathy so frequently present, and the pain and distress associated with the disease usually enable the physician to make the correct diagnosis.

Zoster might be confounded with the peripheral forms of herpes as herpes facialis or progenitalis or with cases with an herpetiform or zosteriform eruption as seen after traumatism or in connection with neurotic conditions as hysteria, etc., or with some cases of vesicular eczema. Some writers regard cases of peripheral herpes as being forms of the same disease as herpes zoster, and one frequently finds in literature such cases described as cases of zoster, especially when the eruption occupies a considerable area. These cases, recurring as they frequently do, have even been described as examples of recurring zoster.

Without entering into a long discussion of this subject, to show the fallacy of such a wide significance to the term zoster, I will consider in this paper herpes zoster as a special disease, distinct from all forms of pure peripheral herpes or other herpetiform eruptions. In peripheral herpes the lesions are frequently bilateral, the anatomical distribution occupying only a part of the territory supplied by a nerve; they form more rapidly; their life duration is usually very much shorter, lasting only a few days—two, three, or four days, rarely a longer period—the lesions are grouped; the groups are usually very small, and few in number; perhaps there is only one group. While there is more or less heat and burning in the part, there is not the severe pain which is generally present in zoster.

If the eruption is situated around the mouth and nose, the acute catarrhal condition usually present makes the diagnosis an easy one. The nearest approach in clinical character of a herpes that I have I now pass round. In it the herpetic

eruption occupies both sides of the face. The eruption will be seen to consist of patches, some containing only a few vesicles, while others contain a large number. The lesions of a patch seem to be of the same age, but the lesions are smaller in size than those of zoster, and they do not coalesce to form bullæ as would likely occur in the latter. If the lesions are confined to one side of the face and reach to the middle line the diagnosis will possibly be in doubt for a short time.

The majority of the cases, if not all of those on record, which have apparently been caused by traumatism, show sufficient variations from ordinary cases of zoster to enable a diagnosis to be made. The term zosteriform eruption which has been applied by some writers to these cases is a suitable one. Some of the cases described as zoster following traumatism are possibly cases in which the traumatism had no part in the production of the disease. So also these cases described as herpes zoster hystericus by Kaposi should be classed as a zosteriform eruption and not cases of true zoster. The clinical symptoms, especially the manner of appearance and mode of extension of the lesions and their course and distribution, show an aetiology distinct from that of the zoster I have been describing.

I saw some time ago a case of herpetiform eruption in the dorsolumbar region in which the distribution of the cutaneous lesions was unilateral, consisting of several patches. The lesions were papulovesicular in character, and those of the different patches were not of the same age. The patches varied in size from half an inch to two inches in diameter and were circular in form. The eruption appeared suddenly, attended by itching. The lesions soon ruptured and were followed by a slight desquamation and a continuance of the itching. There was no tendency to an extension beyond the original size of the patch by the formation of new lesions, and the eruption disappeared in about ten days. This is the history of an outbreak which the patient said had occurred in the same location about once a month for nearly two years. The diagnosis was made of a neuritic or toxic eczema. The urine was examined and found to contain sugar. Zoster was excluded in this case on account of the small size of the vesicles, their early rupture, the itching, the non-tendency to coalesce and form bullæ, and the absence of grouped lesions to form a larger patch. These very similar characters in all cases of neuritic eczemas in patches enable one to make the diagnosis from zoster.

(To be concluded.)

THE THERAPEUTIC VALUE OF MARMOREK'S ANTITUBERCULOUS SERUM.*

By ARTHUR J. RICHER, M. D.,

MONTREAL.

Specific sera for the cure of tuberculosis have during the last ten years occupied the attention of bacteriologists and therapeutists alike.

The last product of the kind, Marmorek's antituberculous serum, is really worthy of more than passing notice. Of the seven advanced cases (some hopeless) which I reported in September, 1904 (1), four have kept up to their improved condition. Since then I have submitted nine incipient tuberculous patients (pulmonary) and the results have been uniformly good. In some instances improvement was very marked within forty-eight hours, accompanied by corresponding modifications in the physical signs. Among the patients of the incipient class thus treated in no single instance did any untoward symptom become manifest. Upon the healthy subject the serum remains without effect. I have inoculated as much as 10 c.c. (in myself) at one sitting without being in any way inconvenienced. In detail I will describe but one, my first incipient case.

A girl of twenty years of age, whose personal antecedents were negative except for an attack of measles at five years and whooping cough at six years; her family history told us that her mother died of pulmonary tuberculosis four years before after an illness of two and a half years. Father living and well. One brother died of tuberculous meningitis eight years before. Four younger sisters living and well.

This patient confessed impaired vitality about six months previous to my seeing her and, when examined, complained of complete anorexia, in fact a perfect disgust for food, dyspnoea upon slightest exertion, accompanied by a dry cough and occasional night sweats with some degree of wasting.

When examined (July 9, 1904) she had a pulse of 110 and an afternoon temperature of 101°. The right lower lobe was the seat of complete consolidation both back and front. Two days later she entered the hospital (private ward) and was kept in bed under supervision for three days without any change taking place in the symptoms; she was then given 5 c.c. of the serum. The next afternoon the temperature had come down to 99.3°; she was given another 5 c.c., which brought down the temperature to 98.3°, after which the afternoon rise never exceeded normal. The pulse was visibly affected, coming down to 80 within five days, while the appetite at once became voracious. Patient was allowed out of bed ten days after first inoculation and was sent to the country, remaining away two months only, during which time she received four inoculations of serum of 5 c.c. each.

When examined again, on September 30th, noth-

* Read at the first meeting of the National Association for the Study and Prevention of Tuberculosis, held in Washington May 18 and 19, 1905.

ing but a small area of impaired resonance could be detected at extreme base behind. She has been examined a number of times since and the lungs are now clear, having remained so since November 1, 1904. The results in the remaining eight patients were quite as good, but, as they were treated more recently, cannot be pronounced upon. A significant fact, however, is that in all incipients thus treated the effect of the serum seems to have been truly specific, not one patient failing to react favorably.

Jacqueroed (2), Arthur Latham (3), de Rothschild and Brunier (4), Montalti (5), Klein and Jacobsohn (6), Schwartz (7), Frey (8), Lemieux, and I have reported upon quite a number of cases, but in all instances these were either advanced, chronic, or quite hopeless, yet with a good percentage of successes.

The method of giving the inoculations in series of six or ten with periods of rest has not seemed to me to be quite rational. The quantity of toxine elaborated by the tubercle bacillus is small and the elaborating is very slow. Why, then, should large quantities of antitoxine be given?

Usually I inoculate 10 c.c. during the course of three days, giving 2 c.c. the first day and 4 c.c. each subsequent day; then I allow a period of rest of at least ten days, sometimes fifteen, proceeding in the same way until 50 c.c. have been injected. After an examination of the patient, if the results are good, I believe it to be wise to continue the inoculations every month, one of 5 c.c. being administered for four or five months in order to keep up the passive immunity conferred by the antitoxine.

ORBITAL SARCOMA: WITH REPORT OF A CASE AND A DISCUSSION OF RADICAL OPERATION, X RAY THERAPY, AND ELECTRO-CHEMICAL STERILIZATION.*

By G. ORAM RING, A. M., M. D.,

PHILADELPHIA,

OPHTHALMIC SURGEON TO THE EPISCOPAL HOSPITAL; CONSULTING OPHTHALMOLOGIST TO THE AMERICAN ONCOLOGIC HOSPITAL; FELLOW OF THE COLLEGE OF PHYSICIANS, ETC.

The legitimate differences of opinion regarding the proper method of attacking this comparatively rare, but always extremely grave, form of malignant neoplasm, will, I trust, abundantly justify the following study:

Agnes Walker, aged 6 years, was brought to my service at the Hospital of the Protestant Episcopal Church, July, 1904. She was seen during my temporary absence by my colleague, Dr. Van Pelt, and by my chief of clinic, Dr. Bromley. The following history was elicited:

The child from birth had been subject to convulsive seizures, which were without periodicity, and were due to gastrointestinal disturbances.

Some obstruction to nasal respiration, with a mucous flow, was noted for some months previous to any postocular development, which symptoms ceased when exophthalmos was first noted. The family history was exceptionally good, and as regards the subject in question, negative.

The vision was apparently normal in each eye; in the right eye mobility was unimpaired, media clear, fundus showed entire absence of gross lesions. No exophthalmos. Left eye, exophthalmos pronounced, the globe being pushed forward quite three quarters of an inch, the additional displacement being downward and slightly outward. Mobility was especially impaired in the vertical meridian.

The left globe was normal, barring some engorgement of veins externally, as well as those radiating from the centre of the disc.

It was impossible to press the globe back into the orbit. Examination over the globe, as well as over the temple, with the stethoscope, failed to reveal either murmur or pulsation. Palpation under the orbital rim, near the inner canthus, indicated a solid nodular growth, extending toward the outer orbital margin, and apparently well back and downward toward the floor. It was firmly fixed and was likewise without fluctuation and pulsation. Preauricular and cervical glands were not involved. The lids were stretched, especially the upper, and showed a purplish discoloration, with marked venous distention.

At the time the child was admitted to the hospital, July 24th, the exophthalmos was increasing, and Dr. H. C. Deaver was asked to see the

* Read before the Ophthalmic Section of the College of Physicians of Philadelphia. December, 1904.

case in consultation. He advised ligation of the internal carotid, which was promptly and most skilfully done by him.

For two weeks the growth seemed to remain in abeyance, when the parents insisted on removing the patient to her home for a week; at the end of which time she returned with a distinct increase in its proportions, a new nodule being easily felt at the upper and outer orbital margin.

The case was now placed under my care and enucleation of the eye and growth advised, with possible orbital evisceration.

My colleague, Dr. Joseph S. Gibb, examined the nose and throat, transilluminating the maxillary and frontal sinuses. The results were negative.

At my request, my friend and former teacher, Dr. Risley, kindly examined the little one, and, while inclining to my diagnosis of orbital sarcoma, suggested an exploratory incision, with a view of establishing the diagnosis with certainty, relating to me the case of an adult patient who presented a somewhat similar train of symptoms. The diagnosis of sarcoma, in this instance, had been made by three ophthalmic surgeons of wide experience. Notwithstanding this Dr. Risley decided to make an exploratory incision, that is to say an external canthotomy followed by an incision into the most pronounced portion of the so called malignant growth, only to find the case one of benign frontal sinus disease, appropriate treatment of which caused immediate and pronounced betterment of all the symptoms.

Barring this suggested modification by Dr. Risley, all of the surgeons who had examined the patient agreed as to the need of operative measures for the removal of the growth.

Osteoplastic resection of the outer bony wall of the orbit, after the method of Krönlein, was carefully considered, but the position of the growth made such operative interference inadvisable.

On October 11th, under ether anæsthesia, with the assistance of my colleague, Dr. Joseph Gibb, the outer canthus was divided with a free incision down to the periosteum.

This was followed by a second incision just within the upper orbital margin, beginning with a point corresponding to the external, and extending to the internal canthus.

Thus partly freed, the upper lid was turned backward, and with a slight further dissection the growth was partially exposed. Careful palpation confirmed my previous judgment that the growth did not involve the frontal sinus, but extended along the roof of the orbit from the internal to the external border.

Its further reach was well down to the orbital floor posteriorly, making enucleation of the eye absolutely necessary.

This was followed by a dissection of the growth, which was rather difficult, especially above. Indeed it was loosened at that point by inserting the closed scissors between the orbital wall and the growth, thus in part shelling it out.

There was a free hæmorrhage which was readily controlled. The orbit was carefully explored

for any remaining foci of induration. The outer canthus was restored with several stitches, and the orbit packed with iodoform gauze, moistened with sterile unguentum petrolati.

At the end of forty-eight hours, when the wound was dressed, there was a moderate swelling of the tissues surrounding the seat of operation and some œdema of the right eyelids. The temperature did not rise above 100.4° , and dropped to normal on the fourth day. The child was permitted to get out of bed at the end of two weeks.

The pathological report, made by Dr. Edward A. Shumway, is as follows: The tissue submitted for examination proved to be a round cell, non-pigmented sarcoma, which had invaded the connective tissue of the orbit. There is a moderate amount of inflammatory reaction, and part of the tissue stains poorly, either from necrosis, or from degenerative changes subsequent to the operation.

Dr. William Egbert Robertson, pathologist to the Hospital of the Protestant Episcopal Church, also made a thorough examination of a portion of the growth and reported it as a round cell sarcoma (non-pigmented).

My personal experience in this type of disease in addition to the history herein reported, is limited to one other case.

A young man otherwise healthy came to me with an orbital sarcoma, which in this instance, followed the kick of a horse on the right temple. The growth extended into at least two of the accessory sinuses and was regarded by Dr. Richard Harte, the general surgeon on duty at the time, and by myself as inoperable. Coley's fluid was given a fair trial, but was of no appreciable avail. This experience occurred several years ago, before we had any knowledge of x ray therapeutics.

It is well known that retroocular sarcomata originate mainly in the connective tissue of the orbit and less frequently from the lacrymal gland, and the bony wall or periosteal lining.

It is fortunately true that the tendency of orbital tumors is to extend forward and outward, rather than backward toward the brain, but when we consider that such a growth may penetrate the optic foramen or superior orbital fissure into the middle fossa, and that in the event of caries or absorption of the roof of the orbit may find its way into the anterior fossa, it would seem but reasonable that in view of a possibly successful operative outcome, radical measures are abundantly justified. The chances of recurrence are greatly reduced if the growth is encapsulated. If the tumor reappears, we assume that a nidus of disease was allowed to remain, or that a new secondary growth has developed.

Quite frequently metastatic growths appear in distant organs and occasionally within the skull

cavity; and as Bull has said, "the more developed the cellular element, the more rapidly does the sarcoma grow and the farther does it extend along the small blood vessels and lymphatics."

As the secondary growth is richer in cells than the primary, it is likely to develop with much greater rapidity and it is our purpose to inquire whether in the event of such development, especially if it is at or near the seat of the original disease, we may not attack it with a reasonable promise of success by the application of one or other of the more recent modifications of the electrical currents.

Before doing so, however, it may be well to consider the following brief references to the method of treatment advised by the authors and compilers of several of our modern text books on ophthalmology. These will serve to indicate what has been the general trend of treatment of this most important and discouraging type of disease.

That these suggestions are likely in future to be materially modified by the further development of electrotherapeutics admits, I think, of little question.

Fuchs states that orbital sarcomata are rounded, rather soft, and sharply defined because enclosed in an envelope of connective tissue, and he believes that small, encapsulated sarcomas can be cleanly enucleated with preservation of the remaining orbital contents. Large tumors, if not circumscribed, of course demand exenteration. Noyes advises early and complete removal. De Schweinitz writes, "if the sarcoma is encapsulated, it should be removed with preservation of the eyeball, if possible," but adds, "if the tumor is malignant, the eye should, in most instances, be excised with the entire contents of the orbit." If originating from traumatism, he regards operative interference as distinctly contraindicated. No mention is made of the sarcomata of young children as being especially subject to recurrence.

Dr. de Schweinitz told me that personally he had seen but one case of orbital sarcoma in a child where, I believe, because of evidences of systemic involvement, no operative measures were considered.

W. T. Shoemaker, in a chapter on orbital diseases of unusual merit, in the recent work of Ball, suggests early removal, accepting the modern view that every primary malignant growth is at first purely local and furthermore agrees that malignant tumors are more safely removed with all the orbital contents. The best results claimed by the general surgeons for operations for malig-

nant growths, according to this writer's figures, range from fifteen to twenty-five per cent.

Reeve, in the Posey and Wright treatise, advises early removal by operation of orbital sarcoma; but later modifies this statement in the announcement that the consensus of opinion is against operation in orbital sarcoma of children, inasmuch as they are apt to be of the round cell variety and, therefore, most malignant. They are held to be inoperable in the sense of assured and possibly hastened recurrence.

Dr. Herman Knapp, than whom no one perhaps has had a more extended experience in this type of disease, advises me that all the orbital sarcomas upon which he has operated have recurred, with one exception where he made a very extensive and radical removal. It was on the temporal side. All the soft parts in the lateral side of the orbit were removed, including the ocular muscles and the periosteum. The eyeball shrank and was finally attached to the bony wall of the outer side. The patient was a young man otherwise healthy. The operation was performed twenty-five years ago. His last visit to Dr. Knapp was made about three years since.

Dr. Knapp has had no experience in the use of the x rays, or with other means than extirpation.

Dr. Buller, of Montreal, in the *System* by de Schweinitz and Randall, advises early and complete removal.

In a recent letter received from Dr. Buller he very kindly sent me a photograph of a fibrosarcoma of both orbits, involving the whole periosteum of both orbital cavities which produced symmetrical proptosis:

"The growths were removed as completely as possible without destruction of the eyeballs, but there was already blindness from pressure on the optic nerves. The child was apparently well for some months, when fresh growths made their appearance about the scalp and head. After this, the patient's health failed rapidly and he died of exhaustion some months later. This case is not recorded and is different from any case Dr. Buller has ever seen."

Dr. L. Webster Fox, in the *Annals of Ophthalmology* of the present year, and again in his recent text book, reports a very favorable result in the treatment of a case of sarcoma, involving the orbit and the maxillary and ethmoidal sinuses. The case was clearly inoperable and was apparently cured by about fifty exposures to the x ray.

Dr. Fox's experience has been so uniformly unfavorable as regards recurrences after orbital excision for sarcoma, that he is strongly inclined invariably to refuse to operate.

Desiring to have an expression of opinion regarding the results of x ray treatment of sarcomata, I wrote to a number of the gentlemen especially identified with that line of work and have been favored with replies, a few of which I briefly append:

Dr. Charles Lester Leonard has had excellent results in sarcomata of face and neck, and has seen similar good results in the practice of friends in various parts of the country. The brilliant results achieved by certain workers in the field of Röntgen therapy must be ascribed to advances in technics. Superficial lesions will yield to almost any technics. Success in treatment of the deeper growths has resulted in a better adaptation of the various qualities of this agent to the cellular character and relative situations of the various lesions in different portions of the body. This adaptation is not yet sufficiently accurate to produce uniformly good results. While the x ray treatment has a beneficial action in recurrences, the effect is less brilliant than upon the original growth.

Dr. Kassabian has utilized this method of therapy in upwards of thirty cases during the past five years. Five of the thirty cases were primary, the remainder recurrent and evidencing signs of general sarcomatosis. Under heroic dosage of x rays a temporary alleviation of pain and diminution of secretion were noted. The primary cases were submitted to the rays from three to four months; of the thirty patients studied, all died. No orbital case was seen and the average age of the patients was fifty years.

Dr. Pfahler, in addition to the case reported by Dr. Fox and himself of orbital sarcoma, reports an angiosarcoma of the face completely removed; an osteosarcoma of face treated for one year and arrested; a round cell sarcoma of lip and nostril and antrum and an angiosarcoma of cheek improved; other advanced cases treated with no apparent result.

Being somewhat conversant with the method of treatment of malignant growths by electrical sterilization successfully inaugurated by Dr. G. Betton Massey, of our own city, and having in mind the utilization of this process in the event of a recurrence *in loco*, I asked Dr. Massey for an expression of his experience in the treatment of orbital sarcoma in children and likewise his opinion regarding the probable outcome of the application of the method in this particular case, with a description of the technics. Dr. Massey's reply is as follows:

"Until a method is discovered whereby these apparently parasitic implantations can be combated by serum treatment, it is evident that our chief recourse must be some form of removal or destruction of the infected tissues, and electrochemical sterilization offers several very important advantages as to operative procedure in accomplishing this. These advantages adapt it pe-

cularly to orbital growths of this nature, owing to their deep penetration, wide bases of contact with surrounding tissues, the free vascular supply of both the growth itself and of its peripheries.

"By electrochemical sterilization we may, within a few minutes, bloodlessly devitalize the growth itself, and carry the sterilization with great precision not only to the irregular limits of the penetrating neoplasm, but beyond the limits into the healthy tissues, thus not only devitalizing all infected cells of the growth proper, but sterilizing a narrow region beyond which the infected cells may be latent. A further advantage is that the edge of the necrosed area thus produced is sealed temporarily, preventing both operative infection and absorption of the chemicals, which drain away as the slough is thrown off by the natural forces.

"In small sarcomata, the method is not only ideal and free from risk, but should present a large percentage of absolute successes.

"In large growths, we have to encounter not only the possibility of failure to destroy all outlying cells, but the risk to the cerebral structures from large currents and the later risk of secondary hemorrhage, if large vessels, supplying the growth, have not been destroyed beyond the diseased points, for diseased vessels are likely to fail to close properly at the line of demarcation when the slough separates.

"A remarkable case, not heretofore reported, came under the writer's attention in 1890. A boy, 5 years old, received an injury to the right eye, when he was 4 years old, necessitating enucleation of the eyeball. One year later, when he was first seen by the writer, a tumor projected from the orbit as large as a man's fist, with a pedicle filling the entire orbit. The tumor projected beyond the face at least five inches, and was a most horrible deformity and source of suffering to a remarkably pretty little child.

"Knowing but little of the limitations of the cataphoric sterilization and destructive process at the time, an effort at relief was made, the child being placed under ether, and as much as 1,200 milliampères applied with several mercury-coated zinc points attached to the positive pole of the battery, which were thrust into the base of the growth, while the negative pole was pressed against its tip, thus preventing the brain from being a part of the circuit. The puncture points bled very freely, showing the extremely vascular nature of the growth. As the current was turned on, the zinc mercury points were ionized or dissolved, and the growth quickly necrosed in its whole extent into a whitish gray mass. The current was turned off at the end of fifteen minutes, the negative pole transferred to a pad on the patient's back, and the current turned on again in this monopolar manner, the current now traversing the brain itself, doubtless in a concentrated current through the optic foramen. This was done in order that the base itself should be adequately sterilized. Unfortunately my notes fail to state the strength of the current attained in this way, though it is thought to have been about five hundred milliampères, for the pulse and respiration failed immediately and the child was dead.

Efforts at resuscitation were continued for some time, but ineffectually.

"In a previous case of sarcoma of the lower portion of the orbit and within the antrum, in an adult, five hundred milliampères had been used with good effect on two occasions, resulting in a notable arrest of the progress of the growth; and, more recently, 350 milliampères had been applied in the very apex of the orbit in a case of rodent cancer, resulting in cure. Judging from these experiences, I should limit a monopolar application in this situation, where much of the current may traverse the cerebral structures, to between 350 and 400 milliampères in an adult, and a still lower current in a child.

"I wish to add that such currents are required only in a major application to a large growth. Small growths may be destroyed by one or more minor applications under the influence of cocaine or eucaine."

The following conclusions seem warranted from a study of these methods:

1. The difficulty in accurate diagnosis under certain conditions entirely justifies an exploratory excision with removal of a section of growth for microscopic study, said exploration likewise serving to determine the ramification of the tumor.

2. The brilliant results achieved by a number of accurate observers in the field of Röntgen ray therapy justify the immediate tentative application of the method before any radical operation is attempted. If unsuccessful in removal of the growth, the virulence of the latter will probably be decreased and the dangers of metastasis lessened. (Leonard.)

3. If the sarcoma is encapsulated, operative intervention without orbital evisceration promises a successful outcome.

4. In view of the almost constant recurrences after orbital evisceration, the removal of the growth itself is regarded as sufficient unless the periosteum or bony wall is involved.

5. The encouraging results reported from the cataphoric sterilization of malignant growths in other parts of the body seem to warrant the utilization of this method in the orbit, due care being exercised as to strength of current used. (Massey.)

6. Future experience must determine whether better results will be achieved by using this method for the original growth, or reserving it for recurrence *in loco*.

7. If operation has been performed and the growth has recurred, we have at command these two valuable methods of attack.

Note, May 23, 1905. As a matter of precaution, x ray applications were begun at the end of the third week after operation and continued at varying intervals until the present writing (eight months after operation), without the slightest evidence of recurrence.

1000 CHESTNUT STREET.

THE DETECTION OF METHYL ALCOHOL.

By HEYWARD SCUDDER, M. D.,

NEW YORK,

MEMBER OF THE CHEMISTS' CLUB.

In a recent number of this *Journal* Dr. Wiley gave directions for a test for methyl alcohol which need some explanation in view of the present general interest in the subject of the use and toxicity of wood alcohol.

The test was devised by Dr. Mulliken and myself in order to furnish a rapid means of detecting methyl alcohol in the presence of ethyl alcohol (ethyl alcohol is the ordinary alcohol of commerce, known also as grain alcohol). The essential features are the oxidation of methyl alcohol to formaldehyde by a heated copper spiral and the detection of the formaldehyde by resorcin in the pressure of concentrated sulphuric acid. Strong alcoholic solutions should be diluted with three volumes of water before oxidation. After oxidation, one drop of a one half per cent. solution of resorcin is added and the mixture is poured down the side of a test tube containing about two cubic centimetres of concentrated sulphuric acid, held in a slanting position so that the solution does not mix with the acid, but rests on top of it. In the presence of formaldehyde a ring, white at first then red, forms at the junction of the two layers. If more than a trace of formaldehyde is present, on gentle shaking, flocks of a characteristic red color appear through the upper layer. Acetaldehyde, the oxidation product of ethyl alcohol, gives a ring and flocks of a yellow or brown color when similarly treated.

Phloroglucin and sulphuric acid give no satisfactory distinction between formaldehyde and acetaldehyde, so far as my experience goes. Dr. Wiley tells me that he will publish further details on this point. It is possible, however, to use phloroglucin in alkaline solution as will be shown later.

IMPROVED TESTS.

Trillat's test, recommended by Dr. Wiley (abstracted in the *Analyst*, 24, 212), can be carried out satisfactorily only by an experienced chemist. Very small variations in the procedure or in the purity of the reagents affect the test in such a way as to render the conclusions of no value. Several chemists who have worked with it have published statements that it cannot be relied on to distinguish between methyl and ethyl alcohols. The test is of value if carried out carefully with a full understanding of the possible sources of error.

Dr. Mulliken and myself published in the *American Chemical Journal*, 24, 444 (1900), an improved test for methyl alcohol, which is much more delicate and not much more complicated than our original test. The difference is, that after oxidation the solution is freed from acetaldehyde by boiling. For ordinary work the boiling can be done in a test tube, stopping when there is no odor of acetaldehyde. For more delicate and satisfactory work the boiling is done under reduced pressure at a low temperature.

Haigh has recently published a test (*Pharmaceutical Review*, 21, 404) in which after oxidation with a copper spiral the filtered solution is boiled in a test tube to remove acetaldehyde, is then poured into a porcelain dish, and an alkaline solution of phloroglucin added. This gives a red color with formaldehyde that remains for two or three minutes. With acetaldehyde there is a faint red color that quickly disappears. The test is simple. But at times I have had trouble with it, since the distinction between the two aldehydes is one of degree of color and of permanence. A weak solution of pure methyl alcohol may give a color that fades so quickly that one cannot be sure that methyl alcohol is present.

GENERAL CONSIDERATION OF TESTS.

No test, dependent on the formation of an odor or of a color, can be relied on under all circumstances. This fact, of common knowledge, is usually forgotten even by chemists of considerable experience. Tests in ordinary use are devised for special cases where only a limited number of foreign compounds are present, and may fail entirely if any other compound is present. In medical work the best known instance of this is the effect of drugs and of compounds formed pathologically in the tests for albumin and sugar in urine.

To be certain that any particular compound is present, it is necessary after making a color or odor test, to isolate the compound in a fairly pure state and form some derivative of it that has a definite melting point or boiling point. The combination of these two tests gives cumulative evidence of great value.

But in cases of daily occurrence, as in this test for methyl alcohol, it is possible to be quite sure of a test if certain precautions are taken to remove compounds that might interfere. In testing for methyl alcohol the chief compound that gives trouble is ethyl alcohol. All the tests recognize this fact and various methods are adopted

to prevent its interfering. In a wine or liquor there may be a number of other compounds that will render any particular test useless. The removal of such compounds is often a matter of great difficulty. The subject is treated quite fully in the last article by Dr. Mulliken and myself. The following general principles are taken from that article and from tests that I have made since its publication:

1. No test involving any preliminary treatment of a solution (such as oxidation) can be relied on, if the original solution before this treatment gives a reaction with the reagents used for the final test.

2. If phenols, alkaloids, or organic bases are known or suspected to be present, this preliminary test of the original solution must always be made.

3. If the original solution becomes turbid or opaque after the addition of two volumes of water, it must be purified before testing.

4. It is always advisable to distil a solution that is to be tested, and only to test that part of the distillate that comes over between 50° and 100° C. The distillation is much more effective, and smaller amounts of methyl alcohol can be detected, if some fractionating device is used. A Hempel tube about 20 centimetres long and two centimetres wide, filled with glass beads, answers most purposes.

FORMALDEHYDE FORMED FROM ETHYL ALCOHOL, ETC.

It might be supposed since the final test is for formaldehyde that a more delicate test for formaldehyde would be of advantage. This is not the case, since ethyl alcohol and many other compounds when oxidized by heated copper give sufficient formaldehyde to be detected by any very delicate test. This can readily be proved by a modification of Jandrier's test. A few drops of a saturated alcoholic solution of gallic acid are added to the oxidized solution, which is then run down on top of concentrated sulphuric acid, as in the test with resorcin. If formaldehyde is present a green or blue ring forms at the junction of the layers. This test for formaldehyde is very delicate and satisfactory, not being interfered with by many compounds.

Trillat's test involves a preliminary oxidation by chemical reagents. It is possible that under certain conditions a small amount of formaldehyde may be formed in this test by compounds other than methyl alcohol, thus explaining the misleading results sometimes obtained. At present there is no definite knowledge on this point.

THE EXPERIMENTS OF SAUERBRUCH IN THE FIELD OF ŒSOPHAGEAL SURGERY.

By DEWITT STETTEN, M. D.,

NEW YORK.

During my service in the past half year at the surgical clinic in Breslau I have had the opportunity frequently to assist Dr. Sauerbruch in his recent experiments with the pneumatic cabinet, and have had ample chance to observe its practical working. In the *Zentralblatt für Chirurgie* No. 4, 1905, Sauerbruch has published a preliminary communication regarding certain operative methods rendered possible by his negative pressure chamber, and it is of these that I desire to write.

After the possibility of successful employment of the cabinet had become established, the first and most interesting question to be solved was the feasibility of bringing the intrathoracic portion of the œsophagus into the domain of modern surgery. This was attempted in Breslau both on animals and man, but with unsuccessful results. The difficulty of the œsophageal suture and the susceptibility of the pleura to infection were not diminished by the cabinet and the chances of successful operation upon the œsophagus at first appeared exceedingly slight.

Only during the last three months, after untiring experimenting and endless modification of his operative technique has Sauerbruch been more successful. Indeed, in the past quarter of a year he has positively demonstrated, at least experimentally, that the intrathoracic portion of the œsophagus can be successfully operated upon by the transthoracic route. He has proved that such operations, including resection, are not only feasible, but even simple and comparatively harmless.

The theory of the subject and the almost obvious fact of the superiority of his method are clearly shown by Sauerbruch in several earlier publications, but more especially and at length in the *Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie*, Vol. XIII, No. 3, 1904.

The cabinet is built of glass and iron and capable of being rendered air tight. The size is about 14 cubic metres, allowing ample room for patient, operator, and, if necessary, three or four assistants. The negative pressure is produced by means of an electric suction pump and the density of the atmosphere is controlled by a water valve in connection with a mercurial manometer. A reserve hand pump excludes the possibility of accident due to chance failure of the working of the electric motor. An opening at one end permits the head of the patient to be free and a rubber collar around the neck of the patient is a simple device to prevent leakage of

air. The anæsthesia is given from without. There is also an appliance whereby all parts but the thorax of the patient can be kept at normal atmospheric pressure, thereby avoiding venous stasis; in experiments upon animals, however, this arrangement has been found superfluous.

By means of a two door system people can enter and leave the cabinet, without altering the pressure. The illumination is electric and the connection with the outside world is by means of a telephone.

Aside from a slight feeling of tension in the ears, which rapidly disappears and which can be prevented if the exhaustion is not too rapid, the people in the cabinet experience absolutely no disagreeable symptoms.

As remarked, all the operations were done in this new cabinet under a negative pressure of 10 to 12 mm. of mercury. This permitted absolutely safe operation so far as the question of pneumothorax was concerned. As a matter of fact, this danger no longer enters into consideration. Dogs exclusively were used for the experiments. The opening in the chest was made by means of an intercostal incision, originally proposed by v. Mikulicz at the last German Surgical Congress. According to Sauerbruch, the three main factors of especial importance in the surgical work on the œsophagus are: (1) Strict asepsis; (2) substitution of the Murphy button for the suture; (3) rapid production of adhesions by means of some such substance as Lugol's solution. I might add, (4) the relieving of tension on the operated œsophagus by lodging a part of the stomach in the pleural cavity.

Two operations have been carried out with particular success, namely, œsophagogastrostomy, or anastomosis between the œsophagus and stomach, and resection of the intrathoracic portion of the œsophagus. I shall briefly outline both operations, drawing freely from Sauerbruch's original description.

Œsophagogastrostomy.—The left pleural cavity is opened in the fifth intercostal space. After systematically incising skin, fascia, and muscle layers, the pleura is caught with a forceps and opened with scissors, about in the same manner as the peritonæum is usually opened in abdominal operations. With the finger or a grooved director as a guide, the pleural incision is extended to the limits of the superficial wound. The ribs are separated and held apart by the hands of an assistant.

The lung which of course does not collapse, but which moves regularly in respiration under the wound, is pushed upward by carefully placed tampons; and the aorta and œsophagus, with the anastomosing vagi, are brought into view.

The œsophagus is grasped by a clamp directly above the œsophageal opening of the diaphragm and drawn into the wound. The cardiac portion is thus

put on the stretch and is seen as a grayish white band 1 to 2 cm. in width, just above the diaphragmatic ring. The pleural, and then the peritoneal layers covering this portion, are next divided and in this manner the abdominal cavity is opened. Through this opening the stomach can be easily drawn into the thorax. The vagi should be spared and the oesophagus must not be too extensively isolated from its surrounding tissue.

The female portion of the Murphy button, fixed on an oesophageal bougie, is now passed into the stomach by an assistant from without the cabinet. The operator grasps this half of the button with his right hand, fixes it in the interpleural portion of the stomach, preferably the fundus, while the bougie is withdrawn.

In a similar manner, the male portion of the button is passed into the oesophagus, fixed in a suitable place, and turned so that the cylinder projects into the anterior wall. By means of small incisions over the respective cylinders, the stomach and oesophagus are opened and adapted to the two parts of the button. Holding the oesophagus in his left, the stomach in his right hand, the operator closes the button. The necessity of any suture at the point of anastomosis is entirely obviated.

After making sure that enough stomach has been lodged in the pleural cavity to allow of the excursions of the diaphragm without tension, a circular suture line is laid at the diaphragmatic ring, connecting stomach and diaphragm. The anastomosis, the diaphragmatic suture, and the pleura are sponged with Lugol's solution, the pleural cavity is irrigated with physiological salt solution, and the intercostal incision is closed in three layers.

Thirteen dogs have recently been operated upon with only three deaths. The cause of death in all three cases was hernia of the stomach, due to imperfect diaphragmatic suture and cardiac compression. All the fatalities occurred many days after operation and could have been easily avoided by careful suture and proper rest.

Resection of the Oesophagus.—The preliminary details are identical with those of the operation already described. The female portion of the button is fixed in the intrapleurally lodged fundus of the stomach, and the male portion in the oesophagus, 2 cm. above the upper limit of the segment, is selected for resection. The button is first closed, the oesophagus is clamped with the Doyen enterotribe, ligated and resected, care being taken not to injure the vagi.

The lower stump is invaginated into the stomach by means of a purse string suture. Invagination is difficult for the upper stump, owing to the friability of the oesophageal tissue, but the upper stump can be easily covered by the intrapleural portion of the stomach. The use of the Paquelin cautery might further simplify matters. The final steps are exactly the same as in the anastomosis operation.

Resection was performed on eleven dogs in succession, with no deaths. As much as 7 cm. was resected in one case.

That these operations are anatomically possible in man has been proved by Sauerbruch by his studies on the cadaver. The conditions correspond for all practical purposes with those found in dogs.

As to the indications for these operations on the human subject, it must be acknowledged that they are extremely limited. The anastomosis might be considered in cases of oesophageal diverticula in the lower oesophagus but, primarily, the procedure would be a rational method of dealing with impermeable cicatricial stenosis at or near the cardia. Although the literature on the subject is rather meagre, I am convinced that these cases are not as rare as is generally supposed. While house surgeon at the German Hospital, New York, in the service of Dr. Willy Meyer in the fall of 1903, I had the opportunity of observing such a case—one which resisted the most carefully planned and elaborately executed attempts to abolish the necessity of a gastric fistula.¹

In malignant stricture, the operation would scarcely supplant the comparatively very much safer gastrostomy. I can conceive of no possibility where, merely as a palliative measure, oesophagogastrostomy might be performed instead of the customary operation, although Sauerbruch seems to think that even here it might be indicated.

Of course, in cases of cicatricial stricture, the operation must be so modified that the gastric half of the button is introduced directly and handled as is usual in abdominal work. The oesophageal portion, however—and this, as Sauerbruch very properly emphasizes, is the important point—can be introduced as was done in the experiments, without the necessity of primary incision or secondary suture.

The resection could be thought of in incipient cancer of the lower part of the oesophagus. When one considers how early diagnosis has been advanced in recent times, by means of perfected oesophagoscopy and the probatory excision depending thereon, the above suggestion may not really seem as fanciful as might at first be assumed.

Sauerbruch asserts that both operations can be performed on the oesophagus as high as the root of the lung and even higher if necessary. Since, however, the higher the operation the greater the necessity for lodging more stomach in the pleural cavity, thereby interfering with the function of the heart, it appears to me that both methods are practically limited to lesions of the cardia and that part of the oesophagus directly above it, necessitating only a small interpleural pouch of stomach.

Sauerbruch has been developing also several other methods, which he will fully describe, giving detailed observations on the above mentioned operations in a monograph soon to be published. He mentions two in his article in the *Zentralblatt*, and

¹ A complete history of this case has already been published by Willy Meyer in the *Zentralblatt für Chirurgie*, No. 26, 1904, in which he suggests the use of the Sauerbruch cabinet as an aid to further operative interference.

I take the liberty of making brief reference to them.

One is an operation in two stages for resection of the upper part of the œsophagus, by means of a plastic substitution of the defect, and the other is a resection of the cardia, also in two stages, by what he calls the invagination method.

The first stage of this latter operation is intrathoracic. The cardia is separated from the diaphragm and invaginated by means of a circular suture. The diaphragm is then sewed to the stomach, as in the other operations, and the thorax is closed as usual.

After two weeks a laparotomy is performed and the stomach is opened. The invaginated cardia is amputated. Suture of the stomach and abdominal wall follows. Sauerbruch thinks that this operation might be applied to cases of circumscribed tumors of the cardia.

Sauerbruch's further publication is naturally awaited with great interest. I do not purpose to anticipate his conclusions, but, in summing up, I wish to lay stress upon certain general aspects of the question.

I freely confess that the direct practical value of these experiments of Sauerbruch is small. I readily admit that the indications for applying them to the human being are very limited, although I most positively believe that such indications do exist.

What I especially desire to emphasize, however, is that the practicability of extensive surgical work upon the œsophagus has become an established fact, without specifically referring to a definite application of these methods. More than this, the experiments show what can be done in the cabinet and, when one remembers that it is considerably less than a year that the new cabinet has been in working order, it requires no great imagination to conceive of the enormous possibilities that have been opened by the Sauerbruch system, not only as regards œsophageal work, but also in the domain of the surgery of the lung itself, the pleura, ribs, mediastinum, and diaphragm.

228 WEST ONE HUNDRED AND THIRTY-EIGHTH STREET.

Medical Society of Northern Virginia.—A meeting of several physicians and surgeons was held on May 17th in Alexandria, Va., when an organization was effected, to be known as the Medical Society of Northern Virginia. The following officers were elected for the ensuing year: President, Dr. R. M. Slaughter, of Fairfax county; vice-presidents, Dr. G. T. Vaughan, of Washington, and Dr. M. W. O'Brien, of Alexandria; secretary and treasurer, Dr. A. A. Rittenour, of Alexandria. The next meeting of the society will be held in November in Alexandria.

A CASE OF TRAUMATIC APHASIA.

By CHARLES PHELPS, M. D.,

NEW YORK.

The comparative infrequency of traumatic disturbance of speech, and the uncertainty which often exists as to its effective lesion, give some special interest to cases like the one which follows:

The patient, a lad 13 years of age, was struck upon the head by a brick thrown from a considerable height. He was at once admitted to the hospital, and after operation two hours later was found to have a compound depressed fracture of the vertex, fissured anteriorly and posteriorly, with one anterior fissure extending into the left middle basic fossa. His temperature on admission was 99°; pulse, 96, and respiration, 28. He was conscious, his mental condition was normal, and he had no general symptoms. Later he vomited undigested food and slept heavily. On the second, third, and fourth days his temperature varied from 99.8° to 100.4°, and his pulse from 90 to 110, and there was still no sign of mental or physical disturbance. An ophthalmic examination made by Dr. Callan disclosed a slight descending neuritis in either eye. At seven o'clock in the evening of the fifth day his temperature was 99.8°, his pulse was 84, and no symptoms had developed. At nine o'clock it was discovered that he was unable to name what he desired—a drink—though he possessed otherwise the power of voluntary speech, and there was no other apparent change in his condition. On the following morning careful examination discovered no symptoms except the disturbance of speech. He had no paralysis or areas of anæsthesia, the reflexes were normal, control of the sphincters was retained, and the special senses were unimpaired. The right pupil was moderately dilated. The temperature through the day was 99.8° to 101°, and the pulse from 80 to 100. His mental condition was alert and intelligent. He understood speech and musical tones, as well as printed and written words, could call to mind objects named, could comprehend simple gestures, and had some power of speech, which progressively diminished through the day. On the other hand, he had total sensory anomia—auditory, visual, tactile, gustatory, and olfactory. He recognized various objects—pencil, paper, orange, salt, sugar, castor oil, etc.—by the several senses, but could give to none a name. This condition was determined by getting negative responses as long as wrong names were suggested, and immediate recognition of the right ones. He could write neither voluntarily nor at dictation. In the morning he could copy fairly well, but only a single word in the afternoon. He could read aloud neither written nor printed words. On the seventh day his general condition remained normal; temperature, 99.8°; pulse, 80. His speech disturbances were unchanged except that his

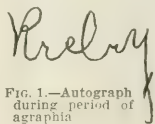

FIG. 1.—Autograph during period of aphasia

vocabulary was still further diminished. From the seventh to the tenth day his temperature still ranged from $99^{\circ}+$ to $100^{\circ}+$ and his pulse from 80 to 88. On the morning of the seventh day two replies to many questions were

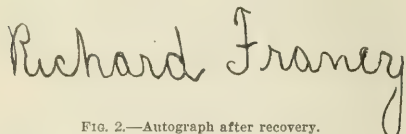

FIG. 2.—Autograph after recovery.

elicited—"good morning" and "I feel better." In the afternoon his only reply to all questions was "Yes" or "No." On the eighth and ninth days he for the first time spoke of his own initiative, and was able to command short sentences, but was still unable to name objects which he recognized. On the eighth day he could read and repeat one, and on the ninth day two words—not more. On the tenth day he could read long sentences, and could name any object presented, as well as write and read writing. On the eleventh day, the sixth of his loss of speech, no aphasic symptoms remained except a little hesitation in reply when questioned too rapidly or for too long a time.

There were no subsequent symptoms, though the patient was detained in the hospital for some weeks, on account of his cranial wound.

The field of ætiological inquiry in this case and in others of its kind can be restricted to traumatic conditions. Its history before and after the injury eliminates the possibility of the existence of any form of toxæmia or of nervous disorder.

The immediate intracranial lesions resulting from traumatism are: Hæmorrhage, epidural, pial, or cortical; limited or diffused meningeal or cerebral contusion; laceration; and a little later a possible meningeal inflammation or cerebral disintegration. The remoter effects of cerebral injury, abscess and atrophy, may be disregarded in this connection.

The reasons for believing that no form of superficial hæmorrhage compressing Broca's convolution or the temporal lobe produces recognizable disturbances of speech have been considered elsewhere¹ with some particularity. Compression to be effective must be applied with force and precision. In epidural hæmorrhages the compressing force is so diffused and minimized by the intervening fibrous shield of dura mater that even when excessive in amount it is deficient in both the essential conditions of sufficiency and concentration. Discarding theoretical considerations, the loss of consciousness which must always attend such cases will itself abrogate speech and all other manifestations of intellectual life. In cases of moderate hæmorrhages of this class, in which

consciousness is retained or restored, there is probably no one recorded in which any form of aphasia has been attributed to this cause; and in none of the writer's personal observations of cumulative epidural hæmorrhages, in which consciousness was gradually lost before death or relieved by operation, were aphasic symptoms recognized at any time during their progress.

Theoretically nearly the same mechanical conditions should render the pial hæmorrhage, or the subarachnoid serous effusion of meningeal contusion, equally ineffective factors in the production of disturbances of speech. Although the dura mater no longer reduces compressive force, the lesser amount of even the largest hæmorrhages of this form compensates for its absence. Practically the observation of a very large number of instances in which such subdural effusions were the essential lesion, and in which consciousness had been retained for a more or less lengthened period, has failed to show even a single one in which the faculty of speech had been disturbed. There have been cases reported in which motor, and perhaps other forms of aphasia, have been attributed to localized pial hæmorrhage, but none in which lesion of the brain tissue has been excluded. In a case previously quoted in this connection, a limited superficial hæmorrhage was regarded as the cause of a loss of speech; and though some improvement resulted from the removal of the clot, the continuance of the aphasic condition for years afterward sufficiently indicates a deeper seated lesion unrelieved by operation. No surgeon of course after trephining for the relief of aphasia would feel justified in subcortical exploration; so that in all such cases the cause must remain undetermined, except as it may be learned from a knowledge of attendant symptoms.

If the hæmorrhage localized in some part of the speech zone proves to be of cortical origin, it must still be regarded as a concomitant rather than as a causative factor in the production of the speech defect. There will be not only the underlying laceration, but additionally the inevitable adjacent limited contusion which may directly involve the centre itself.

In recapitulation, it is to be said of hæmorrhages in general in their relation to aphasia that when large their compression force is too diffuse, and when small that it is too slight to make them effective; or that they are associated with other lesions which are directly operative in its production. It is unnecessary at the present time to raise the question whether intracranial hæmorrhage by simple compression ever directly causes any functional defects, or whether these are sole-

¹ *Injuries of the Brain*, Phelps, 1897-1900, p. 183.

ly dependent upon nutritive changes induced by coincident circulatory disturbances.

The cause of traumatic aphasia, then, must be sought in lesion of the brain tissue which forms the speech centres involved. This lesion is a contusion with or without laceration. It is a hyperæmia and œdema in greater or less degree, limited or diffuse, often with punctate hæmorrhagic extravasations, and in a certain number of cases accompanied by laceration of the cerebral cortex, which is primary, or of the subcortex, which is likely to be secondary and due to disintegration of tissue by continued intracerebral hæmorrhage.

The writer's record of personal observations of head injuries now numbers 958 cases, in rather more than 2 per cent. of which there was some degree or form of aphasia. Seven cases were fatal, and of these five were the subject of necropsy, all of which exhibited well marked lesion of the cerebral tissue. In three of them there was laceration of the left temporal convolutions, in one hæmorrhagic softening of Broca's centre, and in one, not properly in this series, there was structural change, due to displacement and infiltration in the course of a tumor's growth; and all had been attended by general symptoms of severity indicative of cerebral lesion. The operative case revealed only a small clot and an "apparently normal cerebral surface," but as there had been distinct symptoms of cerebral trauma, and the aphasia was unrelieved by operation, there can be no doubt that the effective lesion was subcortical and that the small hæmorrhage was without significance. There is no difficulty in explaining cases of aphasia which are immediate and permanent, or at least long continued, and accompanied by high temperatures, loss of rectal and vesical control, hemiplegia, and mental impairment, on the justifiable theory of cerebral laceration and disintegration. Even in such cases, unless following pistol shot wound or other positively known direct injury, there still may be doubt whether with or without laceration in other regions of the brain the lesion of the speech centres may not be the simple form of contusion. It has not proved to be the fact that a diagnosis of laceration in cases of cerebral contusion is in all cases possible.

The larger class of traumatic aphasias, transitory in character and accompanied only by trivial general symptoms, must be regarded as the result of contusion of a lower grade in which the hyperæmia and œdema are in more moderate degree. The post mortem inspection of cases of cerebral contusion shows these characteristic conditions, not only in widely varying degree,

but often confined to definitely limited areas or even to individual lobes. The observation of symptoms has equally shown this variation in degree and localization. It has also shown that the circulatory disturbance and serous accumulation are unstable, increasing and diminishing at times in the progress of the case to recovery.

The intercurrent of aphasia in the course of recovering cases of cerebral contusion is explicable only by some reference to the progressive pathological changes which occur in this form of injury. The primary effect of violence applied to the head, when sufficient to produce symptoms is, observing a distinction made by Crile² between collapse and shock, cerebral collapse, a suspension of function in greater or lesser degree of the cerebral vasomotor centres, not necessarily attended by an extension to the general vasomotor system. This is immediately followed by a paralytic distention of the cerebral arteries and veins and a condition of capillary anæmia. If the injury is sufficiently severe, and the vascular disturbance is not at once relieved, minute thrombi are formed in the smaller vessels with punctate hæmorrhagic extravasations into the tissues of the region involved. After the lapse of an appreciable interval of time the brain tissue becomes œdematous and swollen. These several pathological conditions, according to their limitations of degree and extent, are attended by corresponding symptoms. From an extremity of violence life may cease almost at once from anæmia of the respiratory centre. The usual primary indication of cerebral injury is unconsciousness, due to the more general anæmia, and its degree and prolongation remain the measure of damage done during the whole primary period of simple vascular disturbance. At its maximum it is profound and prolonged; at its minimum it is scarcely more than a momentary mental confusion or transitory somnolence. Life may terminate during this period; recovery may ensue before the secondary process has begun; primary unconsciousness may merge in its later form; or after an interval, in which consciousness is more or less completely restored, it is again lost or clouded from the later process of increasing œdema and the nutritive changes by which it is accompanied. During the continuance of these periods of primary and secondary vascular and nutritive disturbance many other so called pressure symptoms are manifest, the consideration of which is not essential to the present purpose. If to the intracerebral pressure there should chance to be added an intracranial compression from some form of hæmorrhage or

² George W. Crile, *Blood Pressure*. Cartwright Prize Essay for 1903. Phila., 1903, p. 19.

from a pial serous effusion, symptoms of course may be more severe and more rapidly developed. If some cerebral centre is at the same time lacerated, focal symptoms will be immediate, and will be evident with the return of consciousness, and in some instances at an earlier period; and as the lesion will be permanent, or at least of long continuance, the functional loss will be of corresponding duration; or if such centre is involved in a limited contusion, the loss or impairment of function will occur only in the later stage, when nutritive disorder has been intensified. As these later functional losses are the result of temporary conditions, they are also temporary, and as both vascular currents and serous exudations are subject to variation, they are also often variable in degree and sometimes recurrent. Illustrations of such transitory defaults in function are not infrequent. Transient and inconstant paralyses, anæsthesias, and paræsthesias, as well as aphasias, will be found in the record of many cases; and by the process of exclusion they can be attributed to no other cause than the changes which have been noted as occurring in and limited to the centres themselves.

The case detailed in the beginning of this article becomes comprehensible in the light of these pathological considerations. The early vomiting and somnolence of this patient, and the later slight optic neuritis, indicate some general contusion, while the lack of these symptoms makes it clear that it was inconsiderable in degree. The later development of speech disturbances further indicates a special lesion of the speech zone, as might naturally follow a fracture of the left middle basal fossa, while their postponement till the fifth day and their transitory nature still further indicate that the lesion was progressive or secondary and not destructive in character. These conditions can only be fulfilled by the acceptance of the facts of cerebral contusion as they have been here stated. The escape of the auditory and visual word centres from implication was probably due to a limitation of the lesion to the inferior portion of the zone and failure of the œdema to rise to their level.

The manner in which fatal pressure in cerebral contusion is brought about has been variously explained, and though the question is admittedly not within the scope of the present paper, it is of sufficient interest to justify brief reference. The theories of von Bergmann,³ Hill,⁴ and Courtney,⁵ are familiar. The most recent and most satisfac-

tory exposition is that of Cannon,⁶ founded upon experimentation made in the Physiological Laboratory of the Harvard Medical School. He at first objects to the theories of the writers mentioned that "a mechanical filtration of fluid is called upon to raise a pressure greater than its source," and asserts that "they fail to regard sufficiently the processes occurring in the brain tissue deprived of its proper blood supply." His own views are stated in the following quotation:

"The facts of the ground here covered remain: that injuries to the brain interfere with its proper blood supply, that such interference causes an increased osmotic pressure within the tissues and a consequent taking up of water from the surrounding plasma. The swelling and œdema of the brain after head injuries, therefore, are not wholly due to passive transudation, as Hill and von Bergmann have maintained, but are mainly the result of an active process in the tissues themselves; a force many times greater than blood pressure and amply sufficient to produce all the pressure symptoms and account for all the signs of intracranial tension which the clinical cases of cerebral trauma often manifest."

The ultimate effect of cerebral injuries acting through the primary and secondary disturbances of the circulatory disturbances, as determined by experimentation upon the lower animals, is a disintegration of the nerve cells.

114 WEST FIFTY-FIFTH STREET.

Association of Medical Librarians.—This association concludes to-day its eighth annual meeting in Boston. Discussions have been held on such subjects as the construction of library buildings, the proper situation of reading rooms, book stacks, etc., how to bring the library to the attention of physicians, how to increase the circulation of medical books, particularly in the country, the care of hospital reports, and what books a library with limited resources should procure.

Health Statistics in Chicago During May.—There were 105 fewer deaths from all causes reported in May, 1905, than in May, 1904—representing a decrease of 5.2 per cent. in the annual death rate per 1,000 of population. Among the causes showing increase over May, 1904, are: Acute intestinal diseases, 7; bronchitis, 6; cancer, 4; convulsions, 8; heart disease, 50; measles, 32; nervous diseases, 29; smallpox, 6; suicide, 15; violence other than suicide, 23; whooping cough, 57. Among those showing decrease are: Apoplexy, 16; Bright's disease, 29; consumption, 19; diphtheria, 10; pneumonia, 146; scarlet fever, 8; typhoid fever, 8.

Our Subscribers' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at regular intervals. So far as they have been decided upon, the further questions are as follows:

XXXIX.—How do you treat erysipelas of the face? (Answers due not later than June 15, 1905.)

XL.—What are your views on the obstetrical binder? (Answers due not later than July 15, 1905.)

XLI.—By what honorable means may a young physician best promote his success in practice from the business point of view? (Answers due not later than August 15, 1905.)

Whoever among our subscribers (with the limitations mentioned below) answers one of these questions in the manner most satisfactory to the editor and his advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but NOT REQUIRED) that the answers be short; if practicable, no one answer to contain more than six hundred words.

Only subscribers to the NEW YORK MEDICAL JOURNAL AND PHILADELPHIA MEDICAL JOURNAL (including regular and volunteer officers of the Medical Corps of the United States Army, Navy, and Marine Hospital Service, commissioned or under contract) will be entitled to compete, and all persons known to be engaged in medical journalism are disqualified. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.

The prize of \$25 for the best essay submitted in answer to question XXXVIII has been awarded to Dr. James Stratton Carpenter, of Pottsville, Pa., whose article appeared on page 1112.

PRIZE QUESTION NO. XXXVIII.

THE PREVENTION OF DISEASE OF THE VERMIFORM APPENDIX.

Dr. Gustav Hausser, of Cincinnati, writes:

The prevention of disease of the vermiform appendix resolves itself chiefly into paying strict attention to the hygiene of the gastrointestinal tract, avoidance of constipation, thorough mastication and digestion of proper and well cooked food, avoidance of overindulgence in food and alcoholic stimulating drinks, avoidance of excessive strain upon a relatively weak abdominal wall, proper protection of foreign bodies which may have been swallowed, and the early and thorough treatment of any gastrointestinal disorders.

That the increase of appendicitis during the last decade is chiefly due to more advanced methods of diagnosing, there can be no doubt, the increase, therefore, being more apparent than real, many of these cases formerly passing under various other names, such as typhilitis, perityphlitis, paratyphlitis, enteritis, intestinal obstruction, ovarian inflammations, salpingitis, peritonitis, and numerous others. But that there is some

increase cannot be denied by even the most skeptical, this increase, in all probability, being due to our modern mode of living, whereby in the keen competition of making a livelihood we become careless and negligent of natural physiological needs. If more care were given to natural and hygienic rules, I am quite sure that the percentage of appendicitis cases would be greatly reduced.

The most prolific cause of appendicular trouble is probably overretention of feces, due to the ever prevalent constipation; and to this our chief attack should be directed, as the mass of undigested residue in the cæcum and colon undergoes decomposition, causing irritation and inflammation in and about the region of the appendix, which may result in a simple catarrhal inflammation or infection with the pathogenic microorganisms always more or less present in the large intestine.

The prevention of constipation should begin in early childhood; the mothers should be given explicit instructions as to the importance of carefully watching the stools of their children, who, when old enough to understand, should be impressed with the importance of daily and thorough evacuations of the bowels. Should chronic constipation exist, this should be treated on the lines laid down for this at times obstinate condition—namely, cultivating regularity, a diet of well cooked, but chiefly coarse foods, plenty of vegetables and fruit, a liberal amount of water between meals and at bedtime, outdoor exercise, massage of the abdomen, and, lastly, drugs, in the form of light hepatic stimulants, such as sodium phosphate, Carlsbad salts, etc., and tonics to the intestinal muscular fibres, of which cascara sagrada and nux vomica are types.

It is not only necessary to have daily evacuations, but these should be large, and the patient should feel as if the bowels had been emptied. The bowels may move every day, but yet not sufficiently to empty them, causing small portions of the stool to be left behind, which may remain for days or even weeks, as is frequently shown by large enemas washing out scybala, although the patient may give assurance that the bowels have moved every day.

Secondly, but scarcely of less importance, the subject of proper digestion must be dealt with. The careless and hurried manner of taking food cannot be too strongly condemned; the food not being thoroughly masticated, digestion is frequently incomplete, with decomposition and flatulence resulting. The teeth should be in the best possible condition, and should always be kept so;

food should be thoroughly masticated and the meal never hurried; too much stress cannot be laid upon the avoidance of overindulgence in food and stimulating alcoholic drinks. Never should so much be taken as to cause a feeling of fulness or distress after eating. The food should be well cooked, and any tainted, spoiled, or partially decomposed food should be avoided, as it frequently teems with microorganisms. A diet of a moderate amount of meat with carbohydrates and a large amount of vegetables and fruit is the best under ordinary circumstances.

Should indigestion at any time exist, this should be promptly and thoroughly treated. Decomposition and flatulence should also receive prompt attention, after removal of the offending mass with castor oil or some other equally efficient purge. The drinking water, if suspected of being impure or contaminated by sewage, should be thoroughly boiled before use.

If foreign bodies, such as small particles of lead, beads, fruit stones and seeds, pins, fish bones, etc., have been swallowed, although these are not so much a causal factor of appendicitis as was formerly thought, yet they should receive careful attention, as in a certain percentage of cases, although small, they have been found in or about the appendix; therefore if such bodies have been swallowed, a liberal diet of food leaving a large residue should be given, such as potatoes, rolled oats, and bread. The residue from these food stuffs, surrounding the foreign body, guards its sharp edges and prevents the possible dropping of it into the opening of the appendix or the production of irritation around it.

An attack of appendicitis having occurred and the patient recovered, with no indications for immediate operation, the case then probably being of the catarrhal form, a recurrence may be prevented in a large number of cases by exercising proper care and attention. All of the above named admonitions should be strictly enforced. Particular attention must be given to thorough evacuation of the bowels. All jarring, violent jolting, excessive strain upon the abdomen, as caused by heavy lifting, excessive gymnastics, and violent straining at stool, should be interdicted, for fear of breaking down protective adhesions which may have formed.

If at any time pain or a feeling of fulness is experienced in the region of the appendix, which occurs most frequently after errors in diet or from a sluggish, constipated condition of the bowels, a large soap enema (one to two quarts) or one of olive oil (one pint) should be given, the patient lying upon the back with the hips elevated and

the body slightly inclined toward the left, thus thoroughly flushing the large intestine and removing any feces which may have collected. A purge of castor oil or a saline should also be given per os. Rest in the recumbent posture, until all pain is gone, should be taken, and during this time only a light diet allowed, consisting of, milk, soft boiled or poached eggs, rice, rolled oats, and toast with tea or coffee.

As to operative interference, this should be given consideration in all cases, as the mortality under modern methods of operation is very slight in the simple catarrhal form; and especially is this true of the interval operation, for the dangers attending the leaving of an appendix once diseased in the abdomen far exceed those of the interval operation. If but one attack has occurred, and objections to an operation are made, a second attack may often be prevented by using care and the proper precautions; should, however, a second or third attack follow, it behooves us to urge its removal. Should signs of pus or a fulminating gangrenous form be suspected at any time during or after an attack, an operation is indicated, and it is by far the safer course to pursue, as at any time a general peritonitis may develop.

In conclusion, I wish to state that should any abdominal operation be performed, and the appendix be within easy access and the condition of the patient permit of a prolongation, it is justifiable for the surgeon to remove the appendix and thus save the patient from the danger of any future appendicular trouble.

Therapeutical Notes.

NOTES ON THE NEWER MATERIA MEDICA.

(Continued from page 909.)

Anchylotaphin is a remedy for helminthiasis and is understood to contain 15 per cent. of creosol.

Anticongestine is a mineral poultice compound which consists of a mixture of aluminum and magnesium silicates, with boric and salicylic acids, iodine, potassium iodide, iron carbonate, gaultheria, eucalyptus, thymol, and peppermint, incorporated with glycerin, and put up as a proprietary preparation.

Barutin is described as a double salt of barium-theobromine and sodium salicylate. It is recommended in veterinary practice as a diuretic.

Borol is the name of a mild antiseptic solution intended for use as a gargle or irrigating fluid, which contains sodium borate, 12 grains; sodium carbonate, 12 grains; sodium benzoate, 5 grains; glycerin, 90 minims; eucalyptol, $\frac{1}{4}$ minim; thymol, $\frac{5}{16}$ grain; menthol, $\frac{1}{8}$ grain; oil pinus pumilio, q. s. in each fluid ounce of solvent.

Collaurin is the trade name for colloidal gold, a preparation which is administered internally in the treatment of cancer, syphilis, and scrofulous conditions.

Cysto-lithia is an effervescent compound of cystogen and lithium tartrate, which is put up in tablets containing three grains of each ingredient. The tablets are said to possess uric acid solvent properties, and to act as an alkaline, urinary antiseptic. The tablets are put up and sold in glass tubes, each tube containing 12 tablets.

Dentalone is a saturated solution of chloretone in a liquid composed of oil of cloves, oil of gaultheria, and oil of cassia, which is recommended for treatment of exposed nerves in decayed teeth.

Digitalone is a standardized solution of digitalis of an activity equal to one tenth the strength of fluid extract digitalis U. S. P., which is intended by the makers, Parke, Davis, and Company, of Detroit, for either hypodermic or internal administration.

Dimopyranum is another name for pyramidon.

Emollientine is an ointment containing alum, carbolic acid, isarol, lead oxide, corrosive sublimate, and zinc sulphocarbonate, which is recommended in the treatment of burns, scalds, and lacerations.

Eserine oil consists of a solution of eserine salicylate in olive oil, which affords a painless method of applying eserine to the eye. The solution when made according to directions is sterile and keeps indefinitely; its action upon the eye is asserted to be prompt and painless.

Flavorone is a culture of selected and tested lactic acid germs, which is used for the purpose of ripening cream for butter making and as a ferment in the manufacture of cheese. The ferment is in the form of a powder inclosed in gelatin capsules. It can also be employed for the extemporaneous preparation of a palatable butter-milk.

Formawn is the shorter trade name adopted for chlormethylmenthoether, already described. When brought into contact with warm water formawn splits up into its component parts—menthol, formaldehyde, and hydrochloric acid.

Glyphocal is the name of a compound syrup of the glycerophosphates, containing the glycerophosphates of calcium, sodium, potassium, magnesium, and iron, together with pepsin and diastase. The syrup is also put up in combination with malt extract and hæmoglobin.

Guaia tonic is a preparation of guaiacol and creosote, with quinine, strychnine, and hypophosphites, which has been introduced into medicine by the Searle and Hereth Company, of Chicago, Ill.

Indoform is a salicylic acid methylene acetate, which is produced by the reaction of formaldehyde on acetyl salicylic acid. It is a white pow-

der having a sour, astringent taste, with a melting point of 108 to 109 degrees, which is with difficulty soluble in cold water, but is more soluble in hot water. The preparation decomposes in the system into its constituent parts, and is said to be useful in the treatment of gout, rheumatism, and neuralgia. It is given in doses of one to three tablets, each containing 0.5 gramme, during meals or after eating.

Iodalia is a granulated, saccharated, organic iodine compound in combination with tannin, which is said to afford an agreeable vehicle for administering iodine to children, it being well tolerated. Each teaspoonful is said to contain 1 grain of iodine combined with tannin.

Laxatol is an aromatic laxative tablet, the active principle of which is phenolphthalein.

Methaform is the name adopted by Frederick Stearns and Company, of Detroit, Mich., for a trichlorotertiary butylalcohol. It is another name for a product which is already on the market under several different names.

Phthisocan is the name given to a solution of potassium guaiacolsulphonate in simple syrup, flavored with tincture of orange.

Renetone is a diuretic and antilithic compound which is said to owe its activity principally to the presence of an ammonium formaldehyde compound described as hexacystine. It also contains lithium benzocitrate, buchu, digitalis, tritium, potassium nitrate, and oil of juniper berries, the whole being contained in an alkaline medium.

Sal-Ethyl is represented to be a chemically pure ethyl salicylate, which, it is asserted, has certain advantages over the natural as well as the artificial methyl salicylates. The therapeutical indications are the same as those for oil of wintergreen.

Thyreoidectin is a preparation obtained from the blood of animals which have been previously deprived of their thyroid glands. It is a reddish brown powder, which is put up in capsules containing 5 grains each in bottles of 50 capsules. The dose is one to two capsules three times a day.

Veratrone is a standardized non-alcoholic sterile preparation of veratrum viride, of one fourth the strength of the U. S. P. fluid extract of veratrum, which is intended for administration either per os or hypodermically.

Zinc Perhydrol is a compound which occurs in the form of a white powder, insoluble in water and consisting of 50 per cent. of zinc dioxide and 50 per cent. of zinc oxide. On the addition of acids it liberates hydrogen dioxide. This new preparation is of use as an antiseptic in the treatment of wounds, especially of ulcerating sores, and has the advantage of sodium dioxide of not forming a caustic substance on the addition of acids, or on decomposition in the body, but an inert substance—zinc oxide. It should be used in combination with mineral oils, such as petrolatum, in 10 per cent. ointments.

POLITICS AND SANITATION IN PHILADELPHIA.

Among the results of the recent political disturbance in Philadelphia, by which the mayor of the city appears to have overthrown the Republican organization, which so long has controlled the business of government, it is reported in the newspapers that the number of assistant medical inspectors will be reduced. Two years ago twelve assistant medical inspectors were employed in attending to the placarding of houses in which there were cases of acute infectious diseases. With the inauguration of the new mayor Dr. Edward Martin was appointed director of the Department of Public Health and Charities. Soon after assuming the duties of his office Dr. Martin caused the staff of assistant medical inspectors to be increased to fifty. In addition to their duties of placarding houses for cases of contagious diseases, the inspectors were required to visit the public schools and send those pupils home who presented evidences of infectious or transmissible ailments. At the same time the list of diseases which should be reported to the Bureau of Health was much increased.

We have noted in our columns from time to time the activities of the assistant medical inspectors, and we wish to express approval of the manner in which their work has been done and to say that the policy of Director Martin appears to

be enlightened and modern in every way. The wisdom of a reduction of the force of assistant medical inspectors we question. The removal of these positions from political influence, on the other hand, will be productive of nothing but good. As the service is now conducted, a young physician desirous of a position on this staff must pass a civil service examination, and he is then placed on an eligible list. Before he is appointed, however, he is required to receive the endorsement of the leader of his ward. It can readily be seen that the personal approval of a ward leader is a very important factor in determining a man's capability to fill the position of assistant medical inspector!

These offices pay a salary of \$1,200 a year to each incumbent. Out of this, we understand, the inspector has to make contributions to the Republican city committee, to the ward committee, and to the division committee. In addition, he is called upon to buy tickets to fairs for the benefit of political clubs and to contribute to sundry other causes of a political nature, so that the actual amount received by the inspector is about \$950 yearly. The wonder is that up to the present time the city of Philadelphia has been able to get as good men as have been obtained to accept these positions. We repeat, if these places can be divorced from this kind of politics, nothing but good can come to the Department of Public Health and Charities.

INFANTILISM IN ACUTE DISEASE.

In our issue for May 27th, under the title of Influenza and Preceding Hysteria, we mentioned an interesting report of a case of infantilism, occurring as a feature of influenza, presented before the Paris Hospital Medical Society by Menetrier and Bloch. At a subsequent meeting of the same society (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris*, May 11th) M. Achard reported several instances of the same mental condition occurring late in the course of typhoid fever. M. Achard thought that it was not very uncommon in this disease, and it does not appear from his communication or from the discussion evoked by it that the occurrence is necessarily

connected with any preceding morbid state of the nervous system.

A striking example of puerilism in typhoid fever absolutely unconnected with any such preceding pathological condition was mentioned by M. Siredey. The patient, a man forty-nine years old, was of more than ordinary intelligence and occupied a position in business that called for great mental activity. His typhoid fever was severe, defervescence did not begin until the end of the fourth week, and there were so many relapses that his real convalescence did not set in before the middle of the third month. Infantilism accompanied his progress toward recovery, and was of a pronounced character for two weeks. He showed the most eager solicitude concerning matters of no moment, but gave himself no concern about his business affairs, and never spontaneously mentioned his children, to whom he was devotedly attached.

It will be remembered that Dupré attributed the *puérilisme mental* described by him to "*ménin-gisme*," and in the discussion in question some stress was laid on the severe implication of the cerebral cortex and the meninges in typhoid fever, but it seems not altogether improbable that the infantilism is due to simple exhaustion, and this idea appears to be borne out by its occurring late in the progress of typhoid fever, after the beginning of defervescence. In influenza, as we all know, the same exhaustion comes on remarkably early.

A NEW OCULAR SYMPTOM OF EXOPHTHALMIC GOITRE.

In the *Gazette médicale de Nantes* for May 20th M. Teillais recounts having met with three cases of exophthalmic goitre in which a deep brown pigmentation of the cutaneous surface of the eyelids was noticeable. In the first instance he was disposed to regard the phenomenon as accidental, but the second and third examples led him to look upon the pigmentation as intimately connected with the cause of the disease. According to his observations, the brown color is diffused evenly over the lids, being bounded above by the eyebrow and below by the inferior orbitopalpebral furrow. The conjunctiva is not pigmented.

The effect of the pigmentation is to heighten the apparent extent of the exophthalmia and to intensify the fixity of gaze observed in the subjects of the disease.

This pigmentation, though it has been observed by others, is not sufficiently common to be of much diagnostic value, but it does seem to coincide with an unusual activity of the morbid process that lies at the root of the trouble, for it may accompany the onset of the manifestations and then disappear, or it may come on in a late recrudescence. It is not always uniform, Schroetter having observed a case in which irregularity of its distribution was a feature, accompanied with changes in the subcutaneous tissue, both of which phenomena he attributed to an anomaly of the secretory action of the thyroid gland. Teillais is inclined to accept the theory that exophthalmic goitre is due to overaction of the thyroid, while myxædema depends on defective action or absence of the gland, and he cites in support of this view the temporary exophthalmia that sometimes results from excessive thyroid medication.

THE PRICE OF A GENTEEL OCCUPATION.

The ambition to secure bread and butter earning positions in life in the occupations somewhat snobbishly designated as genteel, comprising clerical and professional positions, is rapidly adding a new and important factor in the ætiology of physical and moral degeneracy. The idea that manual labor and mechanical pursuits of various kinds are the very essence of nobility in bread winning is rapidly becoming only a tradition. The children of both the poorer and the great middle class, speaking from the standpoint of material prosperity, have come to consider the occupations of their fathers and mothers as essentially degrading. This growing prejudice of youth against manual labor and in favor of so called genteel occupations is a deadly and insidious social and moral poison. The young man born of industrious, hard working parents scorns his father's mechanical or day labor occupation and aspires to something better. He has perhaps a smattering of education, merely enough to stimulate ambitions that he can never gratify. To him

work with the hands—honest labor—has no features of dignity to commend it. The consequence is he either makes a desperate effort to qualify for the ranks of the already overcrowded professions or enters some clerical occupation, in which his chances in the battle of life are much less brilliant than his father's, whose occupation, while, from the standpoint of the snob, less genteel, was far more productive of material results. The father perhaps has been able to give his family modest comforts and perhaps a few luxuries in life, to which the family of the would-be genteel son, should he be so misguided as to marry and raise a family, is likely to be a stranger.

The daughter of the mechanic or other wage worker sees nothing respectable or ennobling in the use of the broom, the mop, and the washboard, which have been part of the everyday life of the mother who bore her, and yearns for the shop and the store, with their temptations and starvation wages. She as well as her brother has acquired in all probability a smattering of so called education. This faulty education is often just sufficient to excite dangerous ambitions—ambitions that are decidedly the unhealthful product of their environment in the minds of children of the poor. So far as the young girl is concerned, these ambitions are not likely to be gratified legitimately; whither they often lead, every sociologist knows. The daughter of the mechanic and wage worker spurns domestic service and abhors matrimony in her own sphere. Or if she does not altogether spurn domestic service, and is willing to enter matrimony in her own sphere of life, she has a contempt for domestic service, although she is willing to become a slave for the benefit of the man she marries and the family she rears. Where the young woman has a contempt for domestic service, and is adverse to matrimony in her own sphere, the men of the sphere above her are not slow to take advantage of her ambitions, but not always in a way conducive to her best interests in the battle of life.

The physical and moral degeneracy attendant upon overwork and underpay is nowhere so evident as among those engaged in the so called genteel occupations. Malnutrition among the underfed is not so infrequent among genteel workers

as might be imagined. When the individual who is inured to manual labor or to a mechanical pursuit is thrown out of employment, which, by the way, he rarely is, except under conditions for which wage earners are themselves largely responsible—for example, in the case of strikes—he has practically no difficulty in reestablishing himself in another job, in which he can make a respectable living for himself and for his family. With the genteel occupant of a clerical or professional position the reverse is true. Great difficulty is experienced in getting a suitable position. The suffering on the part of such an individual is far greater than that of those individuals who are not used to the refinements of civilization, and who indeed have no particular ambition to gratify in that direction. His mode of living and that of his family, if he has a family, are keyed up to a plane from which it is difficult for him to descend without considerable shock to his finer sensibilities. The ranks of the criminal are recruited to a certain extent from those who prove to be the weaker vessels in the struggle for existence among the so called genteel workers. In the case of women so employed, recruits for the grand army of prostitutes are more abundant than in the case of women of a less refined class, who are inured to harder methods of earning a livelihood. Other things being equal, the young man or woman with a trade has, upon the average, a far better chance in the battle of life than the individual of professional and clerical occupations.

A comparison of the combined incomes of a large number of mechanics of the higher grades with the aggregate incomes of a similar number of individuals drawn from the so called genteel occupations is very suggestive. I will mention a case in point. From a certain large city in the United States two representative regiments were recruited for service during the Spanish-American war. One of these regiments, sometimes facetiously termed the "dude regiment," was composed of men from the so called genteel or professional classes. The other regiment, which did not stand so high intellectually or socially, was composed almost altogether of workmen of the higher class, such as machinists and engineers, but to a certain extent was made up of miscel-

laneous wage workers. In estimating the sacrifices that were made by the members of the two regiments, it was discovered that the combined incomes which were lost to the members of the last mentioned regiment amounted to a sum which, in round figures, was three times the amount represented by the combined incomes of the members of the more genteel organization.

The old idea paramount in the minds of our forefathers was that manual labor and mechanical pursuits of various kinds were not only respectable, but an essential part of the young man's education. The old fashioned father believed that his duty was, not only to give his son a fair degree of education, but a trade upon which he could rely for a livelihood and to which he could have recourse at any time in case he should have difficulty in earning a living in some occupation which to him was more congenial. There is a tendency of late in certain quarters to revive interest in manual training of various kinds as an essential factor in education and in the making of useful and self-sustaining citizens. This is a theme which I do not care to elaborate at this time, but that it is a most important one the more progressive and thoughtful practical educators of the world are firmly convinced. The practical bearing of the foregoing lies in the proposition that the rise and fall of criminality, prostitution, pauperism, and, in short, all of the brood of social diseases of which degeneracy is the parent, correspond with the ups and downs of material prosperity of the social integers.

G. FRANK LYDSTON.

VEGETARIANISM.

Dr. John M. Swan, of Philadelphia, has made some interesting observations of a sickly vegetarian, one whose parents and grandparents also were vegetarians, and he reports them in the June number of the *American Journal of the Medical Sciences*. Incidentally Dr. Swan remarks that a strict vegetarian must take a large bulk of vegetable food in order to obtain the necessary amount of protein, and that the large mass of carbohydrates necessarily ingested must hinder the normal chemical processes in the body, on account of the fermentations that are likely to take place in the intestinal tract. "Writers," he says, "seem to be agreed that the use of a strictly vegetable

diet, while it may permit of a normal amount of work at times, will not permit of sustained effort, nor will it allow users to meet sudden calls for increased exertion."

PHLEGMONOUS INFLAMMATION OF THE STOMACH.

Dr. Hermann Merkel (*Centralblatt für innere Medizin*, 1905, No. 10; *Berliner klinische Wochenschrift*, May 8th) reports a remarkable case of this rare affection, one in which the extent of the gastric wall involved was very great. The inflammatory process extended to the serous coat, resulting in fatal fibrinopurulent peritonitis. It is said that thus far only seventy cases of primary diffuse gastric phlegmon have been recorded, and that in only three of them was the trouble associated with other pathological conditions of the stomach. In Merkel's case it took its origin in a chronic ulcer.

THE ESMARCH BANDAGE IN THE HANDS OF LAYMEN.

In these days of "first aid" there is considerable danger that hæmostatic measures designed only for temporary use may be kept in operation long enough to be fraught with danger to the integrity of the distal part of a limb. Among them is the Esmarch bandage, and it would be well to bear in mind that, according to Ahlberg (*Nordiskt medicinskt Arkiv*, xxxvii, 3; *Zentralblatt für Chirurgie*, May 27th), it should not be allowed to remain in place for more than three hours.

News Items.

Society Meetings for the Coming Week:

MONDAY, June 12th.—New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medicohistorical Society (private); New York Ophthalmological Society (private); Medical Association of the Greater City of New York; Society of Medical Jurisprudence, New York; Gynecological Society of Boston; Burlington, Vt., Medical and Surgical Club; Norwalk, Conn., Medical Society (private); Corning, N. Y., Medical Association.

TUESDAY, June 13th.—New York Academy of Medicine (Section in Genitourinary Surgery); New York Medical Union (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Association; Rome, N. Y., Medical Society; Medical Society of the County of Rensselaer, N. Y.; Newark, N. J., Medical Association (private); Trenton, N. J., Medical Association; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioners' Club, Richmond, Ky.; Richmond, Va., Academy of Medicine and Surgery.

WEDNESDAY, June 14th.—Medical Society of the Borough of the Bronx, New York; New York Pathological Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Society for Medical Progress, New York; Philadelphia County Medical Society; Lenox Medical and Surgical Society (private).

THURSDAY, June 15th.—New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Mass., Society for Medical Improvement (private); Medical Society of the City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, June 16th.—New York Academy of Medicine (Section in Orthopaedic Surgery); New York East Side Physicians' Association; Manhattan Medical and Surgical Society (private); Clinical Society of the New York Postgraduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynecological Society.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending June 3, 1905:

	June 3.		May 27.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	727	17	888	19
Diphtheria and croup	320	27	331	26
Scarlet fever	152	14	184	15
Smallpox	1
Chickenpox	113	..	141	..
Tuberculosis	393	142	470	163
Typhoid fever	38	4	32	4
Cerebrospinal meningitis	71	60	76	60
	1,815	264	2,116	287

The German Hospital Training School, of Brooklyn, graduated the following nurses on June 1st: Catherine Vettel, Mary Bryan, Helen Louise Muehlich, Marie Track, Ella Teresa Seaman, Catherine Dorothea Fredericka Ruehs, and May Smith.

Queens-Nassau Medical Society.—At the annual meeting of the Queens-Nassau Medical Society, held at the Nassau County Court House, Mineola, on June 1st, Dr. William J. Burnett, of Long Island City, was elected president and Dr. William Irving Barnes, of Oyster Bay, vice-president.

Manhattan State Hospital.—The eighth annual graduation exercises of the training school for nurses of this institution were held at Ward's Island, New York city, Wednesday, June 7th, at 4 p. m., with the following programme: Overture, orchestra; invocation, by the Reverend Rufus Duff, hospital chaplain; address, by the Honorable John C. Coleman; march, orchestra; address, by the Honorable Homer Folks; presentation of diplomas; waltz, orchestra; address, by the Reverend Thomas J. Campbell, S. J.; benediction, by the Reverend Alfred Blewitt, hospital chaplain; march, orchestra.

A New Downtown Emergency Hospital.—Within the next week a new hospital will be established in the downtown district that will relieve the congestion of the Hudson Street Hospital in cases of emergency. The House of Relief is to be located at 93 Gold Street, in the Printing House Square district. The hospital was to have been opened earlier, but the work was delayed so that it will be another week before patients will be received. The new hospital will take in a district from which all accidents are now taken care of by Hudson Street Hospital. Hereafter the new House of Relief will care for those who are injured along Newspaper Row and at the Brooklyn Bridge entrance.

The Medical Association of the Greater City of New York.—A stated meeting of this associa-

tion will be held at the New York Academy of Medicine, on Monday, June 12, 1905, at 8.30 p. m. Order of exercises: Report of the Committee on the Death of Dr. John H. Hinton, by Dr. Ransford E. Van Gieson, chairman; discussion on Hyper trophy of the Prostate and Its Treatment, to be opened by Dr. Lewis S. Pilcher; Perineal Prostatectomy by an Original Technique, with Illustrations, by Dr. Parker Syms; discussion continued by Dr. Carl Beck, Dr. Willy Meyer, Dr. Ramon Guiteras, Dr. Eugene Fuller, Dr. Robert Holmes Greene, Dr. Joseph Wiener, Jr., Dr. James Pedersen, and Dr. William Bedford Brown. J. Lee Morrill, M. D., treasurer, 67 East Seventy-ninth Street; P. Brynberg Porter, M. D., recording secretary, 150 West Eighty-fourth Street.

Long Island College Hospital.—This institution graduated the following on June 1st:

Frederick M. Albers, Horace G. Baldwin, Oscar Best, Charles F. Baxter, Albert W. Beck, David T. Bishop, Siegfried Block, George E. Borden, Robert O. Brockway, Henry W. Brody, Jacob L. Brower, Julius Cohn, Edward T. Curran, William T. Doran, George M. Dunaif, Willis J. Evans, Israel Feigenoff, John D. Freitag, Jr., Joseph Friedmann, Edward H. Gershenson, Charles Ginsberg, Isaac E. Gluckman, Joseph W. Goldsmith, Henry Goodman, Louis Harris, George H. Hicks, Jr., Moses M. Housepian, A. B., Frank W. Hover, Robert Y. Hubbard, Charles Hyman, Samuel M. Hyman, Gerald Kasper, Ph. G., Henry B. Kessler, Hyman Kleban, Benjamin Kleinberg, Charles Clyde, Herman Levinson, Ph. G., George R. Lewis, William E. Lippold, David Livingstone, John P. Lynch, Morris W. Mootnick, Alexander Nechamkin, Alfred H. Parsons, A. B., Julius Phillips, Edward Precht, Charles Reigod, William Rex, Ph. G., Henry U. Robinson, William H. Rogers, Jr., Ph. G., Samuel Rosenberg, Jacob Rosenbluth, Simon Rothenberg, Irvine J. Russell, Aaron Samuelson, Harry Schneider, Frederick Schroeder, Jr., Ph. G., Adolf I. Schwartz, B. L., B. S., Maurice Schwartz, Martin J. Sgier, Max Slutsky, Joseph W. Stevens, Frank Stockman, Alec N. Thomson, Claude H. Topping, Arthur S. Unger, Theodore L. Vosseler, Ph. G., Egbert H. P. Ward, A. B., Cassius H. Watson, B. S., Daniel D. Whedon, Fred R. Williams, Jean F. Wolfs. Frederick J. Schweigart receives a certificate and will receive a diploma this month.

Personal.—Dr. Charles E. Atwood, who has been connected with Bloomingdale for the past thirteen years as assistant physician, has resigned, and leaves July 1st to spend a year in Europe to complete his studies in various hospitals and laboratories there, after which he expects to return to New York to enter the practice of medicine.

Dr. August Hoch, for about twelve years connected with the psychological laboratory at the McLean, at Waverley, Mass., succeeds Dr. Atwood as first assistant and special clinician, which, it is hoped, will result in an increased activity in the Bloomingdale laboratory.

The Jamaica Hospital has two new house surgeons in Dr. M. Thomas Powers and Dr. Louis Clark, both graduates of the College of Physicians and Surgeons in Manhattan. The former physicians, Dr. J. Cameron Gain and Dr. Morsch, have engaged in private practice. The former will continue in Jamaica and the latter will open an office on Sumner Avenue, Brooklyn.

Dr. Fredric Griffith has been appointed a member of the International Peace Conference, to be held in Lucern, Switzerland. Dr. Griffith attends as the accredited agent of the Pennsylvania State Society.

PHILADELPHIA.

Marriages.—Dr. Benjamin K. Fletcher and Miss Sara Redman were married on June 1st.

Dr. John Cooke Hirst and Miss Maud Wilson Boyd were married on June 1st.

Jefferson Alumni Dine.—The annual banquet of the Alumni Association of the Jefferson Medical College was held in the Bellevue-Stratford on June 1st. Dr. Hobart A. Hare and Dr. J. Chalmers Da Costa responded to toasts.

University of Pennsylvania Alumni.—The alumni of the medical department of the University of Pennsylvania enjoyed an outing at the Orchard, Essington, on June 1st. Athletic sports and a collation furnished the entertainment.

Methodist Hospital Training School Commencement.—Miss Matilda Cantrell Degen, Miss Rosalie Anna Ferree, and Miss Grace Alverson Hayman received diplomas at the commencement exercises of the Methodist Hospital Training School for Nurses on June 1st.

The Annual Meeting of the American Neurological Association was held in the College of Physicians on June 1st, 2nd, and 3rd. The afternoon session of June 2nd was held in the new medical laboratories of the University of Pennsylvania. A smoker was given at the Art Club on the evening of June 1st by the Philadelphia Neurological Society. A luncheon was given at the University Club on Thursday, June 1st, and a luncheon was given at the Art Club on June 2nd.

Scientific Society Meetings for the Week Ending June 17th.—Monday, June 12th, Wills Hospital Ophthalmic Society. Tuesday, June 13th, Kensington Branch, Philadelphia County Medical Society; Philadelphia Pædiatric Society; Botanical Section, Academy of Natural Sciences. Wednesday, June 14th, Philadelphia County Medical Society. Friday, June 16th, American Philosophical Society. Saturday, June 17th, West Philadelphia Branch, Philadelphia County Medical Society.

Philadelphia County Medical Society Programme.—The following will be the programme of the Philadelphia County Medical Society at its meeting, June 14, 1905: Dr. T. Turner Thomas, Fractures of the Head of the Radius; Report of Two Cases; An Experimental Study, Preliminary Communication; Dr. Moses Behrend, A Case of Perineal Prostatectomy Performed with the Aid of Young's Tractor; Dr. W. Wayne Babcock, Cervical Rib with Resulting Gangrene of the Fingers; Dr. L. H. Bernd, Uterorectal Fistula; Operation; Recovery.

Fellowship Foundation for Jefferson College.—Dr. W. W. Keen, professor of surgery in the Jefferson Medical College, has presented \$5,000 to the trustees of the college to found a memorial to his wife, to be known as the Corinna Borden Keen Research Fellowship. Whenever the accumulated income of the principal is \$500 it is to be awarded to a graduate of Jefferson College,

who has graduated not less than one year or more than ten years before, who shall apply it to the expenses of original research approved by the faculty. It is expected that the first award will be made in 1907.

Jewish Hospital Training School.—The commencement exercises of the Jewish Hospital Training School for Nurses were held at the hospital on the evening of May 30th. The following young women received the diplomas of the school:

Miss Rebecca Lipschutz, Miss Gertrude Payton, Miss Clara M. Collins, Miss Olivia O. Oakey, Miss Olga Schoettle, Miss E. M. Henning, Miss Ray Kotinsky, Miss Clara Sanderson, Miss R. Blumstein, Miss Lolo F. Krout.

The Matilda Kaufman gold medal was awarded to Miss Rebecca Lipschutz for the highest general average. A special prize of \$55.00 was awarded to Miss Gertrude Payton for having received the highest average in practical nursing. Dr. Bernard Kohn delivered the address.

The Health of the City.—During the week ending May 27, 1905, the following cases of transmissible diseases were reported to the bureau of health:

	Cases.	Deaths.
Malarial fever.....	1	0
Typhoid fever.....	102	13
Scarlet fever.....	37	7
Chickenpox.....	59	1
Diphtheria.....	69	1
Cerebrospinal meningitis.....	6	1
Measles.....	61	1
Whooping cough.....	32	2
Tuberculosis of the lungs.....	28	56
Phthisis.....	31	37
Erysipelas.....	6	2
Puerperal fever.....	2	1
Tetanus.....	1	1

The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 11; diarrhoea and enteritis under two years, 20. The total deaths were 400, in an estimated population of 1,438,318, corresponding to an annual death rate of 14.46 per 1,000 population. The total infant mortality was 79; under one year, 62; between one and two years, 17. There were 30 still births; 13 males and 17 females. No unusual meteorological phenomena were reported by the weather bureau.

Concerning Physicians' Fees.—On the evening of May 26th, the Philadelphia County Medical Society, the Chester County Medical Society, and the Delaware County Medical Society held a joint meeting at the College of Physicians, which was addressed by Dr. J. N. McCormack, of Bowling Green, Ky., chairman of the organization committee of the American Medical Association. This joint meeting was held in pursuance of a resolution of the State Medical Society directing the censorial districts to hold at least one meeting yearly, at which the societies forming those districts should meet together. In the course of his remarks Dr. McCormack said that physicians in Pennsylvania received less compensation for their services than those in any other section of the country. He advised the physicians in the first censorial district of Pennsylvania to unite in an endeavor to have their services more adequately compensated. In Philadelphia many phy-

sicians gave office advice for fifty cents, and made visits to the patients' homes for one dollar. Many practitioners attended obstetric cases for ten dollars. Such fees he ventured to consider absurd compensation for the service rendered. The multiplication of free dispensaries and the competition of the large number of physicians for practice tended to keep fees down to these figures. He was mindful of the saying that the physician should practise his profession for the good of humanity and not for mere dollars and cents. Among the first duties of the physician, however, was that to his family; to keep them from want during his life and after his death; and that to himself, to provide for his own mental equipment so that his advice might be of the best. On fees such as had been mentioned as illustrations these two objects could scarcely be accomplished. We should like to see Dr. McCormack's views as to the adoption of a uniform scale of fees prevail.

Jefferson Medical College Commencement.—

The eightieth annual commencement of the Jefferson Medical College was held in the Academy of Music on June 2nd. The occasion was marked by the presentation of a portrait of himself to Dr. William S. Forbes, professor of anatomy, by the four classes. The presentation speech was made by Dr. Addinell Hewson. Dr. Forbes was also presented with a silver loving cup by the Medical Alumni Association of the University of Pennsylvania in recognition of Dr. Forbes's services in securing the passage of the anatomical acts of 1867. Dr. George A. Piersol, professor of anatomy in the University of Pennsylvania, made the presentation speech. The degree of M. D. was conferred upon the following candidates by the president of the trustees, William Potter:

Frank Cook Abbott, John Walter Barr, Lawrence F. Berry, Joseph Walter Beyer, Joseph Albert Biello, James C. Borland, Guy A. Brandberg, Arthur J. Brew, Charles P. Bryant, John L. Burkholder, Charles C. Cooner, Frank T. Davis, Jr., Frederick M. Davenport, Seward R. Davison, Robert T. Donnelly, George F. Doyle, Harrison A. Dunn, Edward A. Eichman, Gilbert A. Ferguson, George T. Fluke, Howard G. Fortner, Edgar N. Fought, Samuel Friedenburg, Malcolm Z. Gearhart, William H. Glick, Dayne H. Griffith, John Parker Harley, Charles Garfield Hayes, Louis Benjamin Heimer, William C. Heisey, Daniel W. Henry, John Daniel Hogue, John Robinson Hoskins, Henry O. Jones, Ralph Chester Kell, Frederick W. Killian, Guy A. Knight, Parry B. Larimer, Charles A. Lehman, Charles E. Lerch, Alfred A. Lühr, C. H. McCallum, John M. McCanna, Samuel L. McCarthy, Robert P. McCready, Francis J. McCullough, William J. L. McCullough, Ralph W. McDowell, William B. McKenna, Lloyd Russell Mace, James P. McFarlane, James Carre Magee, Ernest George Maier, Lorenzo F. Milliken, Irvin R. Mohnay, Thomas A. Monahan, Edward L. Morrison, Charles C. Moyer, H. J. E. Newnam, Alex J. Orenstein, Thomas C. Park, Alex B. Raff, Victor M. Reynolds, Edward E. Rhoads, William Fay Ross, John Timothy Ryan, LeRoy H. Saxe, Herbert N. Scheetz, Emil S. Schneider, Louis Schwartz, George Harvey Severs, Thomas Emmet Shea, George Siggins, John Reid Simpson, Frank C. Smathers, Samuel Calvin Smith, Wayne L. Snyder, George Sonneborn, George Sigars Spence, James N. Stanton, Samuel Stern, Harry M. Stewart, Francis X. Strong, Richard F. Taylor, Perry McD. Tibbins, Vere Treichler, Edward M. Vaughan, Isaac R. Vincent, Victor C. Wagner, Raymond K. Weber, Mark Dye Weed, Julius Leon Werner, John Joseph Wiley, Ernst T. Williams, Thomas L. Williams, John D. Wilson, William J. Winters, James W. Wood, Roy Lowry Young, of Pennsylvania; Albert E. Austin, Maximilian D. Bloomfield, Daniel F. Clancy, Edward Cooper, Francis A. Cregg, Fred O. Elder,

Clark B. Holbrook, Harold M. Howard, Hugh E. McCaffrey, Elmer W. Mitchell, Thomas J. Norton, Timothy D. Sullivan, Stephen E. Vosburg, of Massachusetts; Theophilus H. Boysen, Jr., Warren T. Clark, Abraham P. Fishman, Thomas B. Lee, Harry E. Lore, Egbert G. Mackenzie, William A. Robinson, James H. Underwood, Walter F. Wood, of New Jersey; Morris M. Caldwell, Major I. Fleming, James H. Harper, Henry H. Harrison, Livingston F. Johnson, Arthur T. Pritchard, Arthur E. Shaw, Samuel L. Stringfield, of North Carolina; Halsey S. Bramble, Tello J. d'Apery, Alexander Eisenstadt, William H. Ferrier, Edward S. Pope, George A. Riker, Herbert W. Thomssen, of New York; Charles G. Alderman, John N. Eyanson, Samuel A. Mumford, James J. Stanton, Garett Van Sweringen, of Indiana; Clarence F. Bernatz, William F. Brown, Earl C. Carhardt, Charles R. Garrett, Lindus La Rell Riggs, of Iowa; Frank A. Ewers, Charles D. Gamble, Levi A. Ruhl, Edison B. Starr, of Ohio; Walter W. Ellis, Horace E. Evans, Edward M. Vaughan, of Delaware; Ferdinand P. Herff, Rice R. Jackson, Thomas E. Williams, of Texas; Harry B. Hanchett, William H. Tallmadge, Jr., of Connecticut; Hanchey J. Hallett, William H. Nix, of Illinois; Robinson Bosworth, Charles A. Riley, of Vermont; Benjamin F. Shuttleworth, Gabriel F. Tucker, of West Virginia; Ray C. Brown, of Maine; Oliver J. Miller, of Florida; Jesse L. Rains, of Idaho; Sterling P. Rumph, of Indian Territory; John G. Abbott, of Minnesota; Noel C. Womack, of Mississippi; Sidney A. Cooney, of Montana; Charles H. Harmon, of New Hampshire; Fred Jay Ziegler, of Oregon; Howard E. Blanchard, of Rhode Island; Hugh B. Sprague, of Utah; Charles C. Warner, of Washington; Howard McCrum Snyder, of Wyoming; George F. Gootrey, Robert G. Jackson, of British Columbia; Morris Reichard, of Hungary.

Class day exercises were held by the graduating class in the Broad Street Theatre on June 1st. The following were the class officers: President, Ferdinand P. Herff; vice-president, Harry Myrrel Stewart; secretary, Samuel Archer Mumford; treasurer, Wayne Lawson Snyder.

GENERAL.

The Woman's Medical College, of Baltimore, graduated, on May 31st, Mrs. Elsie M. Casey and Miss E. Blanche Stirling.

Richmond, Va., Academy of Medicine and Surgery.—The subject for discussion at the June 13th meeting of this body is Massage, which will be opened with an address by Mr. V. R. Ulrich.

The Türk Festival.—For the purpose of commemorating the notable part taken by Türk in establishing clinical laryngoscopy, the Vienna Laryngological Society has resolved to hold a festival in the year 1908.

A New Orleans Clinic, to be conducted exclusively by women physicians, has been opened at 1824 Annunciation Street, in that city. The attendants are Dr. Sara T. Mayo, Dr. Susanna T. Otis, Dr. Cora Bass, Dr. Elizabeth Bass, Dr. Clara C. Glenk, and Dr. Clothilde Janquet.

Bishops College, Montreal, Medical Faculty.—This institution graduated the following on May 23rd:

F. W. Avis, C. S. Carmichael, R. B. Cunningham, George W. Gallatly, F. D. Gill, E. H. Lawson, Arthur J. Moseley, Horace G. MacKerrow, R. H. McRae, M. W. H. Pitman, N. Schacher, A. H. Silverman, H. M. Vartanian, Paul Villard.

Personal.—Dr. A. M. Fernandez de Ybarra, of New York, has recently been appointed corresponding member and official representative in the United States of the Medical Association of

Puerto Rico. Dr. de Ybarra is special correspondent of *El Siglo Medico*, of Madrid; the *Gaceta Médica Catalana*, of Barcelona; *La Escuela de Medicina*, and *Cronica Médica Mexicana*, of the City of Mexico, and the *Boletín de la Asociación Médica de Puerto Rico*.

Dr. Walter W. Kingsbury has been selected to succeed Dr. Clark K. Peterson as house physician of the Malden, Mass., Hospital, to begin his term on July 1st.

Dr. David Streett, dean of the faculty of the Maryland General Hospital, has announced the hospital staff selected for the ensuing year, as follows: Resident physician, Dr. L. B. Cavens; assistants, Dr. Robert L. Blake, Dr. Ernest H. Gaither, Dr. B. W. Carey, Dr. Clarence B. Collins; in charge of lying-in hospital, Dr. George Rosenbaum; resident pathologist, Dr. L. E. Langley.

Dr. John B. Murphy has resigned the chair of surgery in the Northwestern University, Chicago, and will accept the same position at Rush Medical College. The change from one medical school to the other does not affect the relations the physician holds with Mercy Hospital, of which he will continue to be the chief surgeon. Dr. Murphy has been with the Northwestern University Medical School for the last four years.

Dr. Porter E. Williams, of Bunceon, Cooper County, has been elected superintendent of the Fulton, Mo., Hospital for the Insane for a term of two years, beginning June 13th. Dr. J. F. Harrison, of Benton City; Dr. E. E. Evans, of Hallsville; and Dr. W. C. Lewis, of Pike County, were elected assistant physicians in the institution for a similar term.

The Medical College of Virginia has created the chair of Orthopædic Surgery and appointed Dr. William P. Mathews to the place. Dr. Mathews has been for a long time professor of anatomy, and Dr. Clifton W. Miller was his assistant and demonstrator. Dr. Miller, who is regarded as eminently qualified for the position, will take charge at the opening of the new session this fall.

The Massachusetts Medical Society.—The one hundred and twenty-fourth annual meeting will be held at 9 a. m., Wednesday, June 14, 1905, in the building of the Massachusetts Charitable Mechanic Association, on Huntington Avenue, Boston. Meetings of sections will be held in the Medical Library, 8 The Fenway, on the preceding day, Tuesday, June 13th. The following papers are expected to be heard:

Some Interesting Features Connected with the Outbreak of Smallpox at North Adams, Mass., in 1904, by Dr. L. A. Jones, of North Adams; Ocular Vertigo, of Interest to the General Practitioner, by Dr. B. P. Croft, of Greenfield; A Clinical and Laboratory Study of the Therapeutic Value of Hydrochloric Acid in Diseases of the Stomach, by Dr. R. F. Chase, of Brookline; The Medical Treatment of Hyperacidity and Gastric Ulcer, by Dr. F. C. Shattuck, of Boston; at 4 p. m., Dr. Lewellys F. Barker, late of Rush Medical School, Chicago, professor of medicine in Johns Hopkins University, will give an address on Methods in Medicine; Applied Anatomy of the Frontal Sinuses, by Dr. H. P. Mosher, of Boston; discussion by Dr. H. A. Lohrop; Symptoms and Treatment of Diseases of the Frontal Sinuses, by Dr. F. C. Cobb, of Boston; discussion by Dr. S. J. Mixer; What the Suburban Surgeon is Doing in the Abdomen, and How He Does It, by Dr. C. E. Durant, of

Haverhill; discussion by Dr. M. H. Richardson; Early Diagnosis of the Surgical Diseases of the Urinary Tract, by Dr. Benjamin Tenney, of Boston; The Causes of Disability After Fracture of the Lower Leg (a preliminary report), by Dr. F. J. Cotton, of Boston. At 8 o'clock p. m. in John Ware Hall, the Shattuck Lecture, by Russell H. Chittenden, Ph. D., of New Haven, Conn., Some Problems of Intermediary Metabolism. A Demonstration of Clinical and Laboratory Methods Used in Medicine, organized by Professor W. T. Councilman, and to be conducted as follows: Dr. C. J. Blake, Methods of Diagnosis in Diseases of the Ear; Dr. J. B. Blake and Dr. C. A. Porter, Methods of Physical Diagnosis in Surgery; Dr. J. T. Bowen, Methods of Diagnosis in Skin Diseases; Dr. Richard Cabot, Methods of Physical Diagnosis in Internal Medicine; Dr. H. A. Christian, Demonstration in Pathological Anatomy; Dr. E. A. Codman, Methods in Diagnosis by Means of X Ray; Dr. Algernon Coolidge, Jr., Methods of Diagnosis in Diseases of the Nose and Throat; Dr. R. L. Emerson, Methods in Examination of Urine; Dr. H. C. Ernst, Methods in Bacteriology; Dr. A. H. Gould, Methods in Estimating Coagulation Time of Blood; Dr. R. C. Larrabee and Dr. A. E. Austin, Methods in Examination of Blood; Dr. Timothy Leary, Methods in Legal Medicine; Dr. F. T. Lord, Methods in Examination of Sputum; Dr. P. T. Murphy, Methods in Cytopathology; Dr. Franz Pfaff and Dr. E. P. Joslin, Methods in Gastric Diagnosis; Dr. J. H. Pratt, Methods in Examination of Feces; Dr. J. J. Putnam, Methods in Neurology; Dr. Theobald Smith and Dr. H. W. Hill, Methods Used in Board of Health Examinations; Dr. Paul Thorndike, Methods of Diagnosis in Genitourinary Diseases; Dr. J. H. Wright, Methods of Rapid Anatomical Diagnosis.

At 12 o'clock m. the annual discourse will be made by Dr. Charles A. Drew, of State Farm, Bridgewater. At the close of the discourse the annual dinner will be served, and the Fellows of the society, called in the order of seniority, will march in procession to Grand Hall. Notice will be given ten minutes before the formation of the procession, and in the interval Fellows are requested to assemble in Exhibit Hall.

Statement of Mortality in Chicago for the Week Ending June 3, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's midyear populations—1,990,750 for 1905 and 1,932,315 for 1904:

	June 3, 1905.	May 27, 1905.	June 4, 1904.
Total deaths, all causes.....	467	454	452
Annual death rate per 1,000.....	12.22	11.89	12.18
By sexes—			
Males.....	245	266	277
Females.....	221	188	175
By ages—			
Under 1 year.....	73	99	61
Between 1 and 5 years.....	71	35	32
Over 60 years.....	87	102	95
Important causes of death—			
Acute intestinal diseases.....	23	17	21
Apoplexy.....	11	12	18
Bright's disease.....	37	33	41
Bronchitis.....	14	11	6
Consumption.....	47	62	67
Cancer.....	17	28	18
Convulsions.....	6	7	9
Diphtheria.....	8	1	5
Heart diseases.....	59	43	33
Influenza.....	0	1	0
Measles.....	0	7	2
Nervous diseases.....	24	19	24
Pneumonia.....	40	48	67
Scarlet fever.....	1	0	4
Smallpox.....	0	0	0
Suicide.....	14	0	9
Typhoid fever.....	7	3	8
Violence (other than suicide).....	31	33	24
Whooping cough.....	15	11	0
All other causes.....	95	105	96

Another death from cerebrospinal meningitis—the ninth since the first of the year—occurred in the Cook County Hospital, May 29th. The victim was a resident of the city, a tailoress, aged

22 years, who had not been away from the city recently. There are two more cases in the hospital, both Italian immigrants, recently arrived via New York. Of the nine fatal cases thus far, in five the disease was contracted elsewhere. The diagnosis in six cases was verified by lumbar puncture. The contamination of the public water supply, caused by the excessive precipitation of May—5.14 inches, or 1.64 inches more than the May average of thirty-five years—disappeared during the week. Only a slight increase of the impure water disease death rate has been caused by the May rainfall—not at all commensurate with the degree of contamination shown by the chemical examinations, as interpreted by the standards which were reliable before the opening of the drainage channel. The public health indications at the beginning of June—one of the two most healthful months of the year—are entirely satisfactory.

Licensed to Practise in Louisiana.—The following were licensed on May 8th to practise medicine in Louisiana:

Miss C. C. Jauquet, Stewart C. Johnson, J. T. Halsey, L. O. Clark, Ernest Bloom, J. A. Slack, R. B. Pryor, F. Hamilton, H. R. Shands, J. Santer Mueller, R. A. Kearney, M. D. Haspell, R. E. Chalker, E. J. Riche, J. M. Ehler, J. R. Mahone, Jr., J. A. Seawell, J. E. Henderson, J. M. Mosely, C. B. Harrington, W. A. Fletcher, S. L. Hollingsworth, A. J. Newman, J. P. Freisen, P. J. Kahle, A. K. Naugle, C. E. Lehmberg, C. W. Phillips, B. C. Abernathy, T. R. Sartor, R. H. Wheat, J. H. Norman, Jr., P. B. Salaticht, J. W. Mayes, A. H. Boerey, J. K. Thomb, H. L. Lazarre, J. W. Pluchet, W. A. Boyce, F. O. Darby, G. O. Sanders, F. W. Champerois, John Pugh, C. J. May, C. T. DeLoach, J. M. Wheelis, Charles A. Evans, R. A. Comaux, Howard Clarke, P. J. Kerlin, C. E. Hutchinson, V. B. Reynaud, J. L. Purser, W. H. Brent, W. J. Schmidt, Judge James, A. S. Walker, John Tolson, S. N. Jordan, R. W. Vincent, P. W. Bohnay, J. C. Denman, J. H. Hargrave, J. A. Joyner, M. Williams, W. T. Wilkinson, Jr., F. H. Watson, J. F. Pugh, Jr., J. O. Duhan, L. F. Magruder, J. O. Pratt, H. C. Cole, E. L. Lackert, J. C. Burdette, E. E. Dickinson, T. E. Sanders, M. L. Nance, Jr., E. W. Mahler, J. G. Yearward, F. V. Jordan, J. E. Garrison, A. R. Carter, J. M. Cunningham, S. J. Pate, G. C. Boudousqui, W. T. Jones, F. A. Baker, Louis B. Crawford, H. E. Connor (colored).

The West Virginia State Medical Association held its thirty-eighth annual meeting in the Board of Trade Hall, Wheeling, W. Va., May 24 to 26, 1905. The following papers were read:

The Teachings of Failures, by Dr. F. L. Hupp, of Wheeling; The Palliative Treatment of Prostatic Hypertrophy, by Dr. H. E. Sloan, of Clarksburg; Preoperative and Post-operative Treatment of Surgical Cases, by Dr. J. E. Cannaday, of Paint Creek; Appendical Abscess—Pathology and Treatment—Report of Cases, by Dr. S. M. Mason, of Clarksburg; Injuries of the Head—Report of Cases, by Dr. Henri P. Linsz, of Wheeling; Anatomical and Physiological Principles Involved in the Symptomatology of Brain Traumatism, by Dr. J. Schwinn, of Wheeling; Office Treatment of Rectal Diseases, by Dr. William M. Beach, of Pittsburg; "Symposium" on Pneumonia: Ætiology, by Dr. S. S. Wade, of Morgantown; Pathology, by Dr. L. O. Rose, of Parkersburg; Symptoms and Signs, by Dr. W. W. Tompkins, of Charleston; Treatment, by Dr. L. D. Wilson, of Wheeling; Tuberculosis, by Dr. J. W. Preston, of Keystone; Pseudomembranous Croup, by Dr. S. W. Bush, of Parkersburg; Cases and Experiences of Interest, by Dr. W. H. Sharp, of Parkersburg; Diseases of the Kidneys, by Dr. M. McNeilan, of Parkersburg; Rupture of the Bladder, by Dr. J. R. Cook, of Fairmont; The Importance of Early Diagnosis of Intraocular Lesions, by Dr. H. R. Johnson, of Fairmont; Fikker's Diagnosticum, by Dr. L. O. Rose, of Parkersburg; Drugs and the Diazo Reaction—A

Communication, by Dr. William W. Golden, of Elkins; and Notes on Tuberculosis, by Dr. Andrew Wilson, of Wheeling.

Webster Springs, W. Va., was chosen as the next place of meeting, and the following officers were elected: President, Dr. S. S. Wade, of Morgantown; first vice-president, Dr. G. W. Bruce, of Moundsville; second vice-president, Dr. F. L. Hopp, of Wheeling; third vice-president, Dr. A. S. Grimm, of St. Mary's; secretary, Dr. William W. Golden, of Elkins; treasurer, Dr. V. T. Churchman, of Charlestown; councillors, Dr. A. O. Flowers, of Clarksburg; Dr. A. R. Warden, of Grafton; Dr. W. W. Hunne, of Quinnimont; Dr. W. N. Burwell, of Parkersburg; Dr. T. W. Moore, of Huntington; delegates to the American Medical Association, Dr. J. L. Dickey and Dr. L. D. Wilson, of Wheeling.

Pith of Current Literature

REFORMA MEDICA.

April 29, 1905.

1. Two Cases of Endothelioma of the Stomach (*To be continued*), By ORESTE CIGNOZZI.
2. Contribution to the Treatment of Intestinal Occlusion, By FERDINANDO GANGITANO.
3. The Early Diagnosis of Tabes Dorsalis by Means of the Cytological Examination of the Cerebrospinal Fluid, By GIUSEPPE SEVERINO.

2. Treatment of Intestinal Obstruction.—Gangitano's conclusions, based on a series of several cases, were as follows: Of twelve cases reported, nine were treated surgically, while in two the evacuation of the bowels spontaneously was secured by means of atropine subcutaneously. Atropine injections were tried in seven cases, but failed in five. The dose of atropine varied from one to five milligrammes, and even with the larger quantity mentioned no unpleasant symptoms were noted. The author thinks that surgical methods should be employed only after all medical means have failed. Even in apparently desperate cases, patients recover, but when they are markedly debilitated, the operation is apt to be fatal. The method of choice is laparotomy in the median line, but in exceptional cases a lateral incision may be used. Atropine should be tried in all cases before operating, and in many cases it proves useful after the operation. An incision into a part of the gut close to the obstruction, and the evacuation of the contents, followed by lavage, are steps to be recommended in operating for intestinal occlusion.

3. Cytology in the Early Diagnosis of Tabes.—Severino advocates the use of a cytological examination of the cerebrospinal fluid in the early examination of locomotor ataxia. The sample of fluid is removed as usual by lumbar puncture, and the number of cells and their varieties are noted. If a marked majority of the cells found in the spinal fluid prove to be lymphocytes, then the diagnosis of locomotor ataxia is confirmed. Lymphocytosis in the spinal fluid ranks with

Westphal's sign and the Argyll Robertson pupil in the diagnosis of tabes. The technique used was as follows: With the now classical method of lumbar puncture, eight c.c. of cephalorhachidian fluid were removed. The sample was centrifuged in the electric centrifuge for ten minutes, and the supernatant fluid was decanted. The precipitate was taken up with a pipette, and was distributed over three slides, dried, and fixed with two parts of Nikiforoff's fluid (equal parts of absolute alcohol and ether) and three parts of a one per cent. solution of formalin. After drying once more in the air, the first preparation was stained with eosin and methylene blue; the second with eosin and hæmatoxylin, and the third with Czenzynsky's fluid. The preparations were then examined with a $\frac{1}{15}$ immersion objective. In all three slides the lymphocytosis was found to be very marked.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE.

April 2, 1905.

1. Contribution to the Study of Right Pleuritic Effusions in Heart Disease and in Cirrhosis of the Liver, By VENANZIO GIAUNI.
2. A Case of Paralytic Rabies with Bulbar Syndrome, By PAOLO GALLI.
3. The Inconstant Action of Salicylates in Rheumatism, By ALEARDO CERIOLE.
4. Brief Notes on Quinine Poisoning, By ALFREDO PEREZ.

1. **Pleuritic Effusion on the Right Side.**—Giauni analyzes twenty-five cases of pleuritic effusion on the right side, due to heart disease and cirrhosis of the liver, which he was able to study at the autopsy table after having seen the patients in the hospital. He reviews the various theories that have been offered to account for the origin and frequency of pleuritic effusions on the right side, and draws the following conclusions from his own observations: Effusions in the pleura on the right side are frequently met with in heart disease, especially in the last stages, with cachexia and heart weakness. These effusions occur more often in heart affections due to arteriosclerosis than in valvular disease. The inflammatory nature of the exudate could be demonstrated in the majority of the cases analyzed, and this was in conformity with the views of the French school, as well as those of Villani, although other Italian clinicians, led by Bacelli, assert that these effusions are mechanical in origin. While due regard should be given to the rôle of the azygos vein in the development of the effusions of the right pleural sac occurring in heart disease, it is possible that the five cases in which the author found no signs of a pleurisy, but an effusion of serum in the right pleura, were cases of subacute serous pleurisy, according to Letulle's classification.

3. **Inconstancy of the Salicylates.**—Cerioli takes a rather pessimistic view of the action of the salicylates and cites cases in which their action proved very inconstant. He is inclined to think that the salicylates simply relieve the symptoms, but do not in reality cure the disease or prevent complications on the part of the heart.

They should be used with the same discrimination with which other drugs are employed in other diseases.

ROUSSKY VRATCH.

May 23, 1905

1. A Few Data on the Mechanism of Fractures of the Lower End of the Radius in the Typical Location, and on the Anatomy and Treatment of These Fractures, By N. M. VOLKOVITCH.
2. On the Ætiology of Idiopathic Retropharyngeal Abscesses, By V. K. MENSCHIKOFF.
3. Case of Echinococcus Infection of the Falloppian Tubes, By R. S. KLISITICH.

1. **Fractures of the Lower End of the Radius.**

—Volkovitch treats Colles's fracture by a very simple method in cases in which the fragments remain in place on proper reduction, and in which the patients are careful and intelligent or can be watched constantly. The treatment simply consists in keeping the wrist in the position best adapted for the correct union of the fragments, and, according to Volkovitch, the best position is a moderate flexion of the wrist, combined with abduction toward the ulnar side. Two wads of cotton are placed over the joint, one on the dorsal surface directly over the wrist, and the other at the angle formed by the ulna and the edge of the hand when the hand is bent toward that bone. Soft bandages keep these cotton wads in place. After the first few days, during which rest is enforced absolutely, the patient is allowed to move his fingers and also his wrist, provided only that the wrist be not moved in the direction opposite to that described in applying the bandage. Volkovitch also uses massage early in patients whom he can observe constantly. The massage is also applied in the position mentioned. The manipulations are performed by the surgeon after taking off the dressing, and due care is taken that the bones be not displaced during the process. In cases which require a splint, owing to the impossibility of keeping the parts reduced without it, the author uses a moulded plaster of Paris splint over the dorsal surface, shaped so that the hand is flexed and abducted toward the ulna, as has been indicated. This splint reaches from above the elbow to the roots of the fingers, and should be applied over the naked skin after lubricating the parts with vaseline. The object of omitting all padding is to allow the wrist to move to a certain degree, even in this splint, as the result of the elasticity of the moulded plaster. As an exercise for the fingers of the affected hand, while the splint is in place, he recommends the kneading of a rubber ball placed in the palm. A ball of considerable size is employed, so that both the extensors and the flexors shall have some work to do in grasping it. This exercise must be begun, if possible, a few days after applying the splint, and on taking off the latter, massage and the exercise with the ball are combined to complete the cure. Beck suggested the use of marbles, instead of a ball, and used this means of exercising the fingers two weeks after the fracture.

2. **Cause of Idiopathic Retropharyngeal Abscess.**—Menschikoff examined bacteriologically the pus from four cases of retropharyngeal abscess in children from three months to one year of age. He found that the pus contained a peculiar type of streptococcus, which grew in isolated colonies on plate cultures with hæmoglobin agar. The cocci grew abundantly in bouillon mixed with ascitic fluid, and on staining, their chains seemed composed of a series of diplococci. These chains were sometimes matted in clumps, and attained considerable length. The germ was not decolorized with Gram's stain, and was distinguished from other streptococci, such as those of suppurative conditions, scarlatina, erysipelas, etc., by the fact that its colonies on hæmoglobin agar had brown centres surrounded with lighter areole, instead of being grayish films, as are the colonies of the other varieties just mentioned. The new germ resembled the pneumococcus as regards its cultural behavior in hæmoglobin agar. It was feebly pathogenic in animals, but easily produced suppuration when injected subcutaneously. Its biology and morphology make it a close relation to the *Streptococcus mitior vel viridans* of Schottmüller.

3. **Echinococcus in the Falloppian Tubes.**—The affection described by Klissitch is extremely rare, and only one case of this kind appears in the most complete collection of the literature of echinococcus in the female pelvic organs, namely, that of Franta, an assistant of Pawlik's (*Paris Thesis*, 1901). The woman was thirty-five years of age, a Moldavian living in Bessarabia, the wife of a farmer. For fifteen years she had noticed a slow increase in size of the lower part of the abdomen, and during the last year she had suffered from pains in the pelvis and from a profuse yellow vaginal discharge. Her previous history was negative, and her last labor occurred normally nine years before admission. The abdomen appeared of the size of five months' pregnancy, with a hard, almost immobile tumor in its lower part, dull on percussion, which also could be felt on vaginal examination to lie above and to the left of the uterus. The diagnosis of dermoid cyst was made, but on laparotomy the tumor proved to be an echinococcus cyst connected with the left tube, which was distended to the size of a fist, while the chief tumor was of the size of a newly born child. The tumor was removed by separating its extensive adhesions without opening it, and after the operation its true nature was discovered, as it contained daughter cysts, etc. The patient made a good recovery. Microscopical examination proved that the tumor had developed in the tube and not in the peritonæum.

BOSTON MEDICAL AND SURGICAL JOURNAL.

June 1, 1905.

1. The Experience of Nine Years in the Treatment of Diphtheria with Antitoxine,

By JOHN H. MCCOLLOM.

2. A Description of "Pfeiffer's Disease" (Glandular Fever), with a Report of Two Cases,

By A. H. WENTWORTH.

3. Report on Early Diagnosis of Tuberculosis, By A. C. KLEBS, J. H. MUSSER, F. BILLINGS, J. C. WILSON, and H. R. M. LANDIS.

4. A Consideration of the Pelvic Articulations from an Anatomical, Pathological, and Clinical Standpoint, By JOEL E. GOLDTHWAIT and ROBERT B. OSGOOD.

1. **Diphtheria.**—McCollom's paper is practically a short history of diphtheria as it has manifested itself in Boston. The practical point to be deduced is that much larger doses of antitoxine should be used than is the custom. In the early stages of the disease the author advocates the use of from four to eight thousand units and the repetition of such doses every six or eight hours. He reports cases in which the patients in the course of a few days were given from fifty to ninety thousand units of antitoxine. The paper ends with the following conclusions: 1. Antitoxine is a remedial agent of immense value in the treatment of diphtheria, and should be classed among the great medical discoveries of the nineteenth century. 2. In order to obtain the best results, it is important that the serum should be given at the earliest possible moment in the course of the disease. 3. In attacks of diphtheria of a severe type antitoxine should be given in very large doses. 4. In laryngeal diphtheria, in the majority of instances, intubation is the operation of election.

2. **Pfeiffer's Disease.**—Wentworth reports two cases of glandular fever. The disease is characterized by an elevated temperature lasting for a short time and by a rapid enlargement of lymph nodes in the neck, especially those situated in the sides of the neck along the posterior border of the sternomastoid muscle in the region of the upper third. The disease is further characterized in most cases by the mildness of the symptoms and in all cases by the eventual subsidence of the swollen lymph nodes without the occurrence of suppuration. The etiology of the disease, which is not of very great clinical importance, is unknown.

3. **Early Diagnosis of Tuberculosis.**—Klebs, Musser, Billings, Wilson, and Landis review very briefly the various methods that have been suggested for reaching an early diagnosis in pulmonary tuberculosis. When all is said and done, careful and educated physical diagnosis by the old and well tried methods will give the most reliable results.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

June 3, 1905.

1. Chronic Poisoning by Acetanilide, By D. D. STEWART.
2. Neurasthenia Cured by Exercise and Forced Feeding. Report of Two Cases,

By EDWARD LIVINGSTON HUNT.

3. The Dangers of the Domestic Use of Illuminating Gas and the Means of Avoiding Them,

By HENRY LEFFMANN.

4. Medical Education. With Special Reference to the Subject of Physiology,

By MURRAY GALT MOTTER.

5. Conjunctival Irritation Excited by Proximity to a Horse,

By WILLIAM CAMPBELL POSEY.

6. The Ætiology of Chorioiditis, By C. DREW.

7. The Application of Ice in Lobar Pneumonia,
By P. A. AURNES.
8. The Expansion of Gynæcology. A Suggestion for the
Surgical Treatment of Incontinence of Urine in
Women, By E. C. DUDLEY.
9. Stenosis of the Pylorus in Infancy. An Analysis of
One Hundred and Fifteen Cases (*Concluded*),
By CHARLES L. SCUDDER and WILLIAM C. QUINBY.
10. Ankylosis. Arthroplasty—Clinical and Experimental
(*Concluded*), By JOHN B. MURPHY.
11. Absence of Articulate Speech. Classification of One
Hundred Cases Not Due to Mechanical Faults or
Deafness, By C. H. HENNINGER.

1. **Acetanilide Poisoning.**—Stewart reports a considerable number of cases of chronic acetanilide poisoning. Special attention is given to the condition of the blood and of the urine. The blood picture is quite characteristic. 1. The hæmoglobin cannot be estimated, on account of the presence of methæmoglobin, which gives the characteristic chocolate color to the blood. 2. The red cells are usually reduced in number and are more or less deformed. 3. There is usually leucocytosis. In cases of severe chronic poisoning by acetanilide and related coal tar products the symptoms are usually very similar as concerns progressive mental and physical debility, which later often reaches a high grade. There is cardiac weakness, with more or less pronounced cyanosis. Apart from the usual chocolate hue of the blood so noticeable on puncture, the blood picture, were it not for an almost invariably present leucocytosis, would suggest pernicious anæmia.

5. **Conjunctival Irritation.**—Posey reports three cases of conjunctival irritation produced by proximity to a horse. It has been known for some time that certain animal emanations, of unknown character, are capable of producing asthma or simple nasal irritation in susceptible individuals. It is probable that all these cases belong in one general class.

7. **Pneumonia.**—Aurness believes that the proper application of ice to the chest in pneumonia acts as a specific. At least he has so treated one hundred cases without a death. His method of treatment is given in detail.

8. **Incontinence of Urine.**—Dudley advocates the following operation for the treatment of incontinence of urine in women: An inverted U shaped area of tissue is denuded, the convex part of the U being just below the clitoris and the meatus being at the concave part. Two sutures are made to drag the meatus up to just below the clitoris. The shanks of the U are then obliterated by means of sutures. The article is illustrated.

9. **Pyloric Stenosis.**—Scudder and Quinby conclude in this article their rather elaborate consideration of pyloric stenosis. It is not possible to do more than to call attention to the paper as one well worth reading in its entirety.

10. **Ankylosis.**—Murphy gives the results of his experiments in arthroplasty. He has suc-

ceeded in correcting ankylosed joints by the interposition of fascia and muscle, covered with a layer of adipose tissue. The paper is most elaborate and cannot be condensed.

MEDICAL NEWS.

June 3, 1905.

1. The Prophylaxis of Lobar Pneumonia,
By J. M. ANDERS.
2. Causes Underlying Prolonged Loss of Function in Certain Injuries About the Shoulder Joint—Prognosis—Treatment,
By ALFRED S. TAYLOR.
3. A Plea for Medical Treatment of the Inflamed Appendix,
By A. L. BENEDICT.
4. Late Results of Surgical Treatment in Gastric Ulcer—Preliminary Report,
By JOHN C. MUNRO.
5. The Laryngeal Complications of Typhoid Fever,
By RICHARD H. JOHNSON.
6. Remarks on Rotary Lateral Curvature of the Spine,
By LEONARD W. ELY.
7. The Effect of Intestinal Antisepsis on the Excretion of Hippuric Acid in the Urine, By JACOB B. PRAGER.

1. **Pneumonia.**—Anders's conclusions, much condensed, are as follows: 1. The prevalence of influenza during the last fifteen years has brought about an increased receptivity for and incidence of the pneumococcus infection.

2. Certain degenerative lesions, especially of the cardiovascular system and the kidneys, have shown an increased incidence during the last two decades; and these are found to be associated or antecedent conditions in the majority of cases of pneumonia, hence are probably potent predisposing factors.

3. The indoor conditions during the cold season favor multiplication and propagation of the pneumococcus and at the same time tend to diminish resistance to infection by the specific organism.

4. The aged are peculiarly susceptible to pneumococcus infection, hence their bodies should be kept as strong and healthy as possible, especially during the pneumonia season.

5. To overcome the predominating factors in individual predisposition, special attention must be paid to the subject of ventilation, to appropriate clothing, and the avoidance of agencies that cause degeneration of the heart, blood vessel system, and kidneys, as alcohol, social excesses, an over strenuous business or professional life, and the like.

6. The sputum is the principal source of infection and should be thoroughly disinfected so soon as it is expectorated.

7. A large proportion of the general populace harbors the pneumococcus in the nasopharynx, hence thorough cleanliness and systematic disinfection of these chambers should be carried out during the pneumonia season.

8. Means to prevent dust from accumulating and its daily removal from home and the city streets, are imperatively demanded.

9. Public health authorities should be given full executive power to carry out rules and regulations relative to pneumonia looking to the prevention of its spread.

10. Measures of prophylaxis must accord with intelligent public opinion before they can be rendered wholly efficient either by municipal or private authority.

2. **Shoulder Joint Injuries.**—Taylor asserts that there is an analogy between the arm palsies which are at times noticed in the newly born child and losses of function consequent upon shoulder injuries in the adult. The paralysis in both cases results from the overstretching of the nerve roots of the brachial plexus. The author thus summarizes his views: 1. The paralyzed muscles are in groups corresponding to the exit of their motor nerve supply in the roots of the brachial plexus, from above downward. Spinati, teres minor, deltoid; biceps, brachialis anticus, supinators; entire musculature of the extremity in the severest lesions.

2. The lesion is situated in the roots of the brachial plexus, most commonly at the junction of the fifth and sixth cervical roots, but may involve any portion or all of roots from above downward.

3. The lesion is caused by too great diastasis of the head and neck from the shoulder which results in

4. Overstretching (rupture) of the nerves followed by paralysis, traumatic neuritis, and often cicatricial compression of the nerve with permanent impairment of function.

5. The prognosis is not very favorable.

6. Treatment.—(a) Immobilization of extremity with counterirritation over the nerve roots; (b) later, massage, electricity, etc.; (c) finally, surgical interference in selected cases.

3. **Appendicitis.**—Benedict asserts that a sharp distinction can be drawn between cases of appendicitis that should be treated surgically and those that should not. He further asserts that not one case of appendicitis in ten requires operation, and if we base the diagnosis, as has been seriously proposed by some surgical enthusiasts, on such slight grounds as a temporary pain and tenderness in the region of the appendix, then not one case in a hundred demands an operation.

4. **Gastric Ulcer.**—Munro bases his paper on the study of 146 operations for lesions of the stomach. He concludes that it can be conservatively stated that the surgical results in both malignant and benign cases are steadily improving and correspondingly encouraging; that in malignant or chronic benign ulcer and its sequelæ medical treatment must yield to surgery; that this is true of some forms of acute ulcers; that although the technics has improved to such an extent that the results are better than under medical treatment, nevertheless, the ideal method has not been definitely established. This is the next important problem for surgery to solve. Furthermore, only an approximate diagnosis in surgical cases can be made by medical tests, and until such tests have been proved infallible, it is the duty of the physician to seek surgical advice in every case in which there is a possibility of benefit to be derived from mechanical means.

7. **Hippuric Acid.**—Prager reports two experiments on dogs starved and then fed on gelatin, undertaken for the purpose of solving certain problems connected with the excretion of hippuric acid. He concludes: 1. Feeding with gelatin alone increases the excretion of hippuric acid.

2. When putrefactive changes are increased the excretion of hippuric acid is increased, and *vice versa*.

3. When the intestinal canal is made antiseptic with calomel there is practically no hippuric acid excreted.

4. Intestinal antiseptics have no effect whatever on the excretion of nitrogen.

5. No matter how much gelatin is given, it is completely burned and some of the body's proteid with it.

6. Therefore gelatin never builds up any tissue, although it may to a certain extent protect the body's proteid from decomposition.

MEDICAL RECORD.

June 3, 1905.

1. Inflammatory Disease of the Uterine Annexa and Its Treatment, By H. GRAD.
2. Some Ophthalmic Suggestions, By RICHARD KALISH.
3. The Heart and Circulation in the Prognosis and Management of Pulmonary Tuberculosis, By SILVIO VON RUCK.
4. The Relation of Ethmoidal Inflammation to Asthma, By HENRY COGGESHALL.
5. A Difficult Diagnosis in a Case of Abdominal Pregnancy, By W. S. LANGFITT.
6. A Case of Heroine Habit, By CHARLES E. ATWOOD.
7. Cactus Grandiflorus, By FINLEY ELLINGWOOD.

1. **The Uterine Annexa.**—Grad writes an eight page article on the diagnosis and treatment of inflammatory conditions of the uterine annexa. The paper does not lend itself to condensation, as it covers too large a field.

2. **Ophthalmic Suggestions.**—Kalish's ophthalmic suggestions may be reduced to this: Glasses should be prescribed by an oculist, and not by an optician.

3. **The Heart in Pulmonary Tuberculosis.**—Von Ruck asserts that the condition of the heart and of the circulation has an important bearing on the treatment and prognosis of pulmonary tuberculosis. Tachycardia, after exertion, demands rest more imperatively than a moderately elevated temperature. The proof of this assertion is the object of the paper.

4. **Asthma.**—Coggeshall asserts that asthma is paroxysmal difficult breathing. The disease is inflammation of the mucous membrane in the ethmoid cells. Irritation of branches of the trigeminus or olfactory nerves causes an altered activity in the medulla, that is to say, in the centre of respiration. The result in the bronchial tubes is a vasomotor disturbance or contraction of muscles, or both. Chronic bronchitis, or emphysema, and a dilated right side of the heart, are not asthma. They are sequels to asthma of severity and long standing. Therefore the whole treat-

ment reduces itself to curing the inflamed condition of the ethmoid cells.

6. **Heroine Habit.**—Atwood reports the case of a woman of twenty-nine years who got into the habit of taking from two to four grains of heroine a day by hypodermic injection. She became thin, neurasthenic, and debilitated, her digestion was disordered, and she said she could not sleep, eat, or do anything without a daily resort to the drug. After taking it, she always felt as if she "could do anything." She was cured of her craving for the drug in four days. There was no return of the habit.

7. **Cactus Grandiflorus.**—Ellingwood asserts that this plant is in every way superior to digitalis in affections of the heart. Two to five minims of the fluid extract act as well or better than larger doses. This drug must be given only in atonic conditions of the heart muscle. If there is violent heart action or persistent palpitation from increased tonicities, or if there is increased nervous or muscular tone, it is absolutely contra-indicated.

AMERICAN MEDICINE.

June 3, 1905.

1. Further Remarks on Ischochymia and Its Treatment,
By MAX EINHORN.
2. Bright's Disease in High Official Circles at the Nation's Capital,
By T. L. MACDONALD.
3. Observations upon Amœbas Infecting the Human Intestine, with a Description of Two Species, *Entamoeba Coli* and *Entamoeba Dysenteriae* (*To be continued*),
By CHARLES E. CRAIG.
4. The Office of the Spleen: An Essay in Comparative Physiology,
By EDWARD T. WILLIAMS.
5. Malarial Infection Presenting Symptoms of Multiple Neuritis,
By GEORGE E. PRICE.
6. The Lloyd Reaction for Morphine and Other Alkaloids (*To be concluded*),
By DANIEL W. FETTEROLF.
7. Yellow Fever: A Popular Lecture,
By JAMES CARROLL.
8. The Physician as a Citizen,
By EDWARD N. BRUSH.

1. **Ischochymia.**—Einhorn notes that in two previous papers he has considered the symptomatology of ischochymia or, as the older authors called it, "clinical dilatation of the stomach." In the present paper the author discusses the statistics of the condition, some new points in its clinical course, and its treatment. We give only the author's views regarding treatment. There are two ways of treating ischochymia: 1, Dietetic and medicinal measures (rectal alimentation, fluid diet, lavage of the stomach, bismuth, etc.). 2, Operative procedures (gastroenterostomy, pyloroplasty). These two methods of treatment do not antagonize but supplement each other. The indications for both are fairly well determined, where one ceases the other begins. The indications for medical and surgical treatment of ischochymia may be placed as follows: 1, Benign ischochymia requires, first, medical treatment; if this is unsuccessful, *i. e.*, if after a long period of treatment, the fasting stomach, on a fluid diet, is not empty, but contains food remnants, an operation is advisable. 2, Surgical intervention is also

indicated in benign ischochymia which has developed subsequent to a condition of continuous hypersecretion of gastric juice (preceded by hæmorrhage or not). 3, Malignant ischochymia or one of dubious nature in which, however, a thickening of the pylorus is found, should also be treated surgically (gastroenterostomy, and, if possible, resection of the pylorus).

2. **Bright's Disease.**—Macdonald calls attention to the great number of public men who have suffered and died of nephritis. He asserts that the prevalence of the disease at the national capital is due to the fact that the congregation of so many eminent men in one place leads to a concentration of worries, wealth, and official feasting.

4. **The Spleen.**—Williams concludes a column article as follows: In the young embryo prior to the formation of the spleen, the primitive mesoderm possesses the property of making blood cells. In late embryonic life this property is restricted to special organs and tissues. In adult life it is limited to the spleen in cold blooded animals (fishes and amphibians), while in the warm blooded animals the red marrow continues throughout life to officiate as a subsidiary spleen. In this way nature makes provision for the added number of red corpuscles required by the higher animals for their increased respiratory activity and the maintenance of their bodily heat.

5. **Meningitis.**—Hildesheim has studied the histories of over one hundred cases of posterior basic meningitis, and points out how this disorder stands apart from epidemic cerebrospinal meningitis as a disease *sui generis*. The bacteriology of the cerebrospinal fluid is at present in a very perplexing stage. A diplococcus identical with the meningococcus has been found in nine cases of posterior basic meningitis. Clinically the epidemic disease shares many features in common with the one under discussion. Our knowledge

of the sporadic form antedates the earliest descriptions of the epidemic disease by several years. There is a very definite difference in the age incidence. More than half the cases of epidemic cerebrospinal meningitis occur in persons under ten years of age, while more than half the cases of the posterior basic form occur in infants under one year of age. The protracted nature of many of the cases of the posterior basic disease has no parallel in the epidemic form. Most of the sequelæ of the former are associated with internal hydrocephalus. There is every reason to suppose that inflammation of the meninges not infrequently endures for several months. Amaurosis without optic neuritis is a remarkable feature of the basic disease, and occurs in one third of all the cases. On the other hand, optic neuritis seems fairly common in epidemics. Deafness occurs in the majority of cases of epidemic meningitis, and only rarely in the other form. Skin lesions, although they occur, are much less common in the basic form of the disease.

6. Pneumococcus Serum in Endocarditis.—

Horder and Scofield report a case of pneumococcus endocarditis unsuccessfully treated with anti-pneumococcus serum. The patient, a boy aged 10 years, suffered from a bilateral pneumonia, followed by double empyema, and was just convalescing from rheumatic fever when taken ill. The presence of pneumococci in the circulation was not demonstrated until late in the course of the disease. The serum was given on five days, late in the disease, but no good results seemed to follow its use, the patient dying on the sixty-sixth day of the disease. The leucocyte count was lowered to 11,600, showing that the resistance was much below normal. If we are dependent upon the patient's tissues for their reaction to the stimulus provided by a bactericidal serum, that is, the action is not a direct, but an indirect one, it is easily understood why failure took place in this case.

8. Poltophagy vs. Psomophagy.—

Higgins has studied the importance of thorough mastication of the food. By poltophagy is meant the swallowing of well masticated, finely divided food; by psomophagy, the taking of food by bites. The most simple illustration of poltophagic and psomophagic deglutitions in man is afforded by two ways in which water can be swallowed: (a) it can be swallowed at once by pushing it against the soft palate with the tongue (psomophagy); and (b) it can be swallowed more slowly by employing movements of mastication; as soon as the water is warmed it is swallowed by a series of short deglutitions. The author holds that man is primarily poltophagic, his faculty for psomophagic deglutition being due to the alteration of structure consequent on the assumption of the erect position, the shortening of the maxilla from before backwards, and the consequent vertical disposition of the soft palate. The essential difference between a poltophagic and a psomophagic deglutition is that in the first case an unconscious, automatic, and complicated series of events precedes the entry of the food into the

stomach, whereas in the latter case it is introduced more or less directly.

9. **Vaccination During Smallpox.**—Hibbert has investigated the question as to whether a successful vaccination or revaccination of a patient suffering from a suspicious rash, speaks strongly against that rash being one of smallpox. In twenty cases of undoubted smallpox which were vaccinated or revaccinated after the appearance of the eruption eleven vaccinations or revaccinations were successful. In the greater proportion of the successful cases well marked, typical vaccine vesicles appeared at the site of vaccination. These vesicles became evident from the fourth to the sixth day after the operation and ran the usual course. In some cases instead of the typical vesicle there was merely an indurated raised papule. Ten of the eleven successful cases were vaccinated during the first four days of the disease. It could not be detected that vaccination or revaccination when performed after the smallpox eruption had appeared, had definitely any modifying influence on the rash or on the course of the disease.

By J. M. SHARPE.

1. **Œdema.**—Mann considers the causes and treatment of œdema due to failure of cardiac or renal compensation. In simple cardiac œdema the causal factor is essentially hydrodynamic, its action being mediate; the œdema is not due to back pressure, but chiefly to changes in the vascular endothelium caused by the imperfect supply of oxygen and of nutrient material. The walls become unduly permeable, and the ensuing permeation is augmented by the low blood pressure supply to the kidneys and the coincident retention in the tissues of sodium chloride. Œdema, due to kidney disease, is less readily explained; vascular endothelial changes due to the toxic action of waste products, defective elimination of water by the kidneys, and the occurrence of hydræmic plethora, undoubtedly play a large part. Here, too, there appears to be a close relation between the retention of sodium chloride and the occurrence of œdema. It is a question whether the retention is a historetention or a seroretention. The author does not accept this theory implicitly, but is satisfied that the restriction of dietetic salt tends to promote the dispersion of the œdema of Bright's disease. In the treatment of œdema when the heart alone is at fault, physiological rest

is the most potent of all remedial agents; this comprises the absence of all avoidable acids, mental as well as physical, on the cardiac energy. In most cases of failure of cardiac compensation, rest alone is insufficient to restore it. Of medicinal remedies digitalis stands apart from other heart tonics in respect to efficacy. In some instances the judicious administration of alcohol is of great efficacy in tiding the heart over a critical period, but it must be closely watched. As regards the treatment of renal incompetence, our therapeutical resources have been materially added to by the introduction of the class of diuretics derived from purin. They are methyl substitution products of xanthin or dioxyapurin. They comprise caffeine, theobromine, and the isomer of the latter, theocine. Caffeine is the most powerful cardiac stimulant, theocine the most active diuretic. When the kidneys fail to respond to diuretics, the skin affords an alternative route for the elimination of water and also of the solid urinary constituents. Cathartics, often of service in the treatment of oedema, avail little in the dispersion of oedema. The dietary indications are to avoid excess of proteids, and of any dietetic substances which irritate the renal epithelium or increase the retention of water. Milk is universally held to occupy the first place in the dietary of nephritis, but its exclusive use is not without its objections—for one thing it is too dilute, and involves the taking into the system of too much fluid. A moderate amount of solid food, poor in proteids and sodium chloride, should be allowed. The quantity of fluid allowed should always receive the most careful consideration. The progress of the oedema is ascertained by periodically weighing the patient, whose weight diminishes as the oedema subsides.

2. **Purulent Cavities.**—Woods discusses the treatment of purulent cavities, and attempts to show that simple drainage, so successful in the treatment of soft tissue abscesses, must be largely supplemented in the treatment of chronic purulent collections inside fixed walls. As long as the tissues, whether near or remote, to whose tension the abscess pressure is due, are not distorted beyond their limit of elasticity, increase in the size of an abscess, is followed by a rise in its pressure, while if that limit is passed it results in a fall. If the cavity is large enough, the surrounding tissues lax enough, or the abscess sufficiently slow in its growth, the tendency to spontaneous evacuation after incision may be too feeble to overcome the influence of gravity if the opening is not at the most dependent point. It is clear that the abscess will never heal if the pressure on the pus between the drainage opening and the lowest point of the sac is insufficient. In most acute soft tissue abscesses, such as those of the tonsil, the influence of gravity may be disregarded. The negative pressure of the thorax plays a large part in the prevention of the healing of empyema. To make such a cavity heal at once, we should besides providing an exit for the pus, keep the lung continuously distended so that the pleural layers are in contact. The author suggests that this be done by means of a suction apparatus, the seat of the

wound being made air tight by means of a pneumatic pad through which the drainage tube runs. The apparatus is provided with a manometer by which the pressure can be regulated. The pad once in position, it should not be removed until cure has taken place. The earlier the treatment is begun the better the chances of recovery. The pressure should be sufficient to keep the lung expanded. In rigid cavities, such as the antrum, where the epithelium is destroyed, drainage alone is of no service. The diseased tissue must be curetted, and the raw surfaces allowed to epithelialize; in many cases skin grafting will also be necessary. The beautiful modern operation on the mastoid, consisting of throwing the tympanum, external meatus, mastoid cells, and attic, all into one large accessible cavity in which skin grafting is done, well illustrates this statement.

4 and 5. **Complete Prostatectomy.**—Thomas's article is based on a series of fifteen complete prostatectomies—13 suprapubic and 2 perineal, with 2 deaths. The ages of the patients varied from 56 to 77 years. Freyer's operation was the one performed; surgeons who do it must possess strong talon shaped nails on the forefingers. Weak antiseptic solutions for washing out the bladder are only a source of local irritation, plus the possibility of being absorbed and throwing unnecessary tax on the eliminating organs. Sterilized salt solutions are better because the beneficial effects are really due to the removal of surgical dirt. Antiseptics to be of any germicidal value must be strong; pure tincture of iodine poured into the bladder is excellent to correct septic conditions either at the time of operation or subsequently. It is much better than any powder. Freyer reports a further series of sixty cases of enlargement of the prostate, in which a radical cure was brought about by the total enucleation of the organ.

6. **Tuberculin.**—Brown reports a case of tuberculosis of the bladder occurring in a girl aged 16 years, in which the use of Koch's T. R. tuberculin brought about marked improvement, the disease being apparently arrested. The dose at first was one two hundred and fiftieth of a milligramme, which was slowly and carefully increased to one milligramme. This was given once a week and caused only slight reaction. After three months of the treatment cystoscopic examination showed the ulcers to be healed, but scattered nodules were still present. No tubercle bacilli were present in the urine.

7. **Sea Sickness.**—Sharpe assumes that sea sickness is a reflex action of the stomach, due to a central stimulus, that the reflex action is transmitted to the solar plexus by the vagi, and finally that the stimulus probably originates in disorders of visual accommodation. By paralyzing the accommodation of one eye by means of a mydriatic, it was found that the symptoms were greatly lessened in intensity. Chloral when used in sea sickness requires to be given in large doses—unfortunately such doses act as a gastric irritant, and increase the tendency to vomit; so that when used, it should be given by rectum.

Letters to the Editor.

THE LIBERATION OF FORMALDEHYDE.

NEW YORK, May 17, 1905.

To the Editor,

Sir: We notice in your issue of May 13th an abstract of a report by Henry V. Walker, of the Brooklyn Health Department, on A Simple Method of Generating Formaldehyde Gas, describing a process in which formalin is vaporized by chemical heat, i. e., by the admixture of aluminum sulphate and slaking lime. In this connection permit us to call your attention to the fact that this method is covered by United States Patent No. 665,794, dated January 8, 1901, taken out by the Schering Chemical Works, for which application was made as long ago as June 9, 1899. The following are the claims secured by this patent:

1. The herein described process of evolving disinfecting vapors, which consists in mixing formaldehyde, water, and a body evolving heat in contact with water, in such quantities as will produce sufficient heat to evolve vapors, substantially as specified.

2. The herein described process of evolving disinfecting vapors, which consists in adding burnt lime to a watery solution of formaldehyde, in such quantities as to evolve vapors, substantially as set forth.

SCHERING AND GLATZ.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of Thursday, April 6, 1905.

The President, Dr. RICHARD C. NORRIS, in the chair.

Some Results in Abdominal Surgery.—Dr. GEORGE ERETY SHOEMAKER presented this paper. He said that in a series of one hundred abdominal cases as they had presented themselves at the Presbyterian Hospital in ward and private work, there had been five deaths, two of them inevitable. Of these patients, one was actually dying of general purulent peritonitis, and the abdomen was rapidly incised to liberate pus as a forlorn hope. In the other case of inevitable death, the patient had at the time of operation gangrene and supuration of several feet of small intestine. One of the others was in the sixth week of an acute attack of chronic recurrent appendicitis. One death followed a severe operation for large tubal and ovarian abscesses and a pelvic pus collection which had at various times previously drained into the bowel. One death occurred unexpectedly in a chronic pelvic inflammation case. Of the ninety-five patients who recovered, hysterectomy was done on twenty, only once by the vaginal route alone. The method preferred was supravaginal amputation without drainage. Nine of the hysterectomies were for malignant disease, and the combined vaginal and abdominal route

was here preferred. A primary operation was done for acute or chronic appendicitis in eleven per cent., but taken altogether the appendix was removed in thirty-three per cent. of all abdominal operations.

The method preferred was described. Suspension of the uterus was done but once as an independent operation. The six cases of ruptured uterine gestation sac were variously treated, and all the patients recovered. In the twelve cases of fibroma of the uterus, all were treated by hysterectomy except one, in which myomectomy was performed. There was no mortality. The questions of drainage and abdominal wound closure were referred to. Within a corresponding period 114 minor operations were done, some of them combined. In sixty-eight per cent. of the cases requiring a perineal operation, the anterior vaginal wall was also repaired by the flap excision method.

A Contribution to the Efficiency of Plastic Operations in the Vagina.—Dr. BARTON COOKE HIRST said that in 1,358 perineorrhaphies, 303 anterior colporrhaphies, 625 operations on the cervix, and 86 operations for total prolapse, among 1,582 patients, the following lessons had been learned:

A more frequent injury of the pelvic floor than laceration of the levator ani muscle was laceration and retraction of the transversus perinaei muscle, often associated with injury of the triangular ligament. Laceration of the urogenital diaphragm in the anterior vaginal sulcus was almost as common as laceration of the levator ani muscle and the pelvic diaphragm in the posterior sulcus. The levator ani muscle was frequently torn from its attachment to the pubic bone and the arcus tendineus instead of being lacerated in the middle line of the sulcus. All these injuries could be repaired as well during the puerperium as at any other time if the patient was put on an operating table and a formal plastic operation was performed with sufficient assistance. If the repair of the lacerations in the puerperium was neglected, proctoceles, cystoceles, and prolapsus uteri could be more perfectly and permanently corrected than was usually the case by modification of the ordinary operative technique suggested by a study of the original injury.

If a routine examination in all cases was made, by inserting a forefinger laterally under the skin of the labium majus, above the triangular ligament, within the vaginal introitus, the finger often sank into a deep pocket, frequently reaching to the ischium. If the region was palpated externally, it was found flabby and relaxed and remained so after the ordinary Emmet operation. By palpating with the forefinger inside and the thumb outside the stump of the retracted transversus perinaei muscle was often felt. If the retracted muscle was brought to the median line again and the triangular ligament was restored, a striking difference was observed. A strong musculoligamentous band almost as long as the breadth of two fingers spanned the space between the ischia, the posterior commissure of the vulva, and the anus. The tone and resistance of the diaphragm

of the pelvic outlet were those of a nulliparous woman.

A somewhat wider and deeper denudation was made at the posterior portion of the vulvar orifice than common, and a large curved needle was inserted in such a manner as to catch retracted muscular and ligamentous tissue. It was often necessary to carry its point almost to the ischium. Then by sweeping the handle of the needle holder through half a circle, bringing it below the needle instead of above, the suture of silkworm gut was carried as in the ordinary crown stitch of the Emmet operation.

In prolapse operations this perfect restoration of the pelvic floor was particularly important, but the commonest defect of such operations was an imperfect restoration of the anterior vaginal wall. It was mainly on this account that there had been such a discouraging proportion of failures in the statistics of many operators.

The following technique, in Dr. Hirst's judgment and experience, gave the greatest assurance against a recurrence: The vaginal sulci were denuded as in his operation for cystocele. The sutures were inserted, but not united; in the grip of hæmostats they were laid over the pubes. The cervix was pulled out of the vulva. An inverted shield-shaped denudation was made on the anterior vaginal wall, ending at the circular incision for amputating the cervix. The sutures were a tier stitch on the anterior wall and interrupted sutures for the cervix. The posterior vaginal wall and pelvic floor were usually restored by an extensive Hegar's operation, care being taken to repair the diaphragm of the pelvic outlet. In women of childbearing age, the uterus was suspended as an additional precaution.

Dr. CHARLES P. NOBLE agreed with the president that this paper brought up the whole subject of gynaecology, and the question was, which point to consider. The first point emphasized by Dr. Shoemaker was that of deaths. Dr. Noble's practice had been to give the patient the chances from an operation, unless he thought she was surely going to die. While it added somewhat to the mortality of an institution or private practice, he thought that what surgeons were in existence for was, not to report the least possible mortality by refusing operation in a certain class of cases, but to operate upon every patient who might have her chances improved by operation. This winter he had had the pleasure of saving a number of patients' lives who would have died promptly without operation. He thought this was true of all surgeons every year. He had seen one patient very ill from general peritonitis of several days' duration, due to a necrotic dermoid. The inflammation extended over the peritonæum as high up as could be seen through an incision which extended above the umbilicus. It was back in the kidney regions, and the omentum was so altered that it did not look like omental tissue. The recovery here showed how well some of these apparently desperate cases of general peritonitis would do. Dr. Noble felt strongly that it was the duty of the surgeon to offer up his reputation (if he chose to look at it in that way) for

obtaining uniformly good results as a sacrifice for the good of his patients.

In reference to sarcoma, the case reported reminded him of a case in which he had operated probably twelve years ago, in which there had been a previous operation. When the abdomen was opened the bowels were found adherent. When separating them he came upon a mass of brainlike tissue, quite a little of which tore off, giving plenty for microscopical examination. It was clearly an inoperable case, but the question was, how to control the bleeding, the blood just welling up from the soft tissue. This was stopped by packing the lower part of the abdomen with gauze and putting a bandage around the patient, causing pressure on the intraabdominal gauze. The patient got well. In view of the pathological report of sarcoma, he was still further surprised to have the patient five years afterward come into his office perfectly well. He thought that either the pathologist was wrong or the sarcoma made a spontaneous recovery.

Dr. Noble was interested in one point in which Dr. Shoemaker's practice differed from his, in that he had abandoned the use of douches in perineal operations. Dr. Noble continued the old fashioned method. He was interested to know that Dr. Shoemaker's cases ended in recovery just as well without irrigation as they had before with it, and should be glad to know whether they did any better.

The President thought obstruction of the bowel, early or remote, following coeliotomy, a most important subject. He happened to have a case under his care where he removed a necrotic ovarian cyst a year and a half ago, the patient making an uninterrupted convalescence and recovery. Some fifteen months after the operation he was asked to see her in consultation with her family physician, who thought she had appendicitis. She was sent to the hospital without his seeing her and prepared for operation. He found her in the operating room with a rapid, feeble pulse and stercoraceous vomiting. Upon opening the abdomen he found a similar condition to that described by Dr. Shoemaker. Sixteen or eighteen inches of gut, necrotic and gangrenous, were caught in a band of adhesion between two portions of the small bowel, the band having been converted into a tight ring by a turn of the bowel. The patient improved rapidly after resection of the bowel, and for four or five days appeared to be making an uncomplicated recovery, when she again had alarming symptoms and gave evidence of obstruction with fecal vomiting. He reopened her and found and relieved an obstruction of the small bowel high in the abdomen, near the splenic flexure of the large bowel. She died within twenty-four hours. This was the only case of the kind that he had met with, and it impressed him with the remote danger of this accident after the simplest abdominal section. The necrotic bowel had started a peritonitis which bade fair not to be fatal, when the second obstruction occurred and the reopening of the abdomen was, as usual, too great a tax on the patient. The resection was hurriedly made with the Murphy button rein-

forced with a continuous Lembert stitch. At the autopsy the resection area was found united and the button had released itself and was ready to pass on through the intestine. All experiences of this nature should be reported, and he asked the members to discuss this interesting topic included in Dr. Shoemaker's report.

(To be concluded.)

Book Notices.

Handbuch der Urologie. Herausgegeben von Dr. ANTON V. FRISCH, A. O., Professor der Chirurgie an der Wiener Universität, und Dr. OTTO ZUCKERKANDL, Privatdozent für Chirurgie an der Wiener Universität. Zweiter Band, Wien: Alfred Hölder, 1905. Pp. vi-871.

The second volume of von Frisch and Zuckerkandl's treatise comprises the medical and surgical affections of the kidneys, the ureters, and the bladder, including a section on the nervous affections of the bladder. The first volume of this work was reviewed in these columns about a year ago, when we dealt with the prolegomena and general problems of urology. The third volume, which is soon to appear, will contain a comprehensive treatise on the lower urinary and the genital tracts.

As was foretold in the review of the first volume, this treatise is undoubtedly one of the most exhaustive and complete of its kind ever published. Each section is practically a text book, written by a specialist, and the whole is arranged to reflect that branch of medicine which has gradually differentiated itself during the past decade as "urology," a branch including both the surgery and the medicine of the urinary organs, as well as the subjects which lie in the borderlands of the two.

Essentially the present treatise is an exponent of modern urology, according to the latest researches; yet the subject is presented from the viewpoint of the Vienna school, represented in the present second volume, by Paul Wagner, Julius Mannaberg, Otto Zuckerkandl, and L. von Frankl-Hochwart. Conservatism, tempered with judicious acceptance of the newer facts and theories wherever they apply, forms the keynote of this viewpoint, and the individual authors bring into this work a great thoroughness of clinical detail, an abundant command of technique, and a mastery of the literature of their subject.

The section on the surgical diseases of the kidney, by Paul Wagner, may be favorably compared with the monographs of Küster and of Albarran, but it is not quite so exhaustive as the classical work of Morris, in two volumes. It covers the subject amply and is written in lucid and concise style. Space forbids mention of more than a few points on which controversy has been going on of late. Thus, in speaking of the treatment of suppurative pyelitis and pyelonephritis by lavage through ureteral catheters, the author gives credit to Kelly, Casper, Albarran, and Stockmann, in the order named, for employing this method, and agrees with Israel, Rovsing, and others in pronouncing this treatment useless in pyelonephritis. Nothing is said of the use of lavage in so called simple catarrhal pyelitis and in chronic nephritis, as advocated by Ayres, but, in contradic-

tion to Ayres, Wagner found gonococci but very rarely in the pelvis, and says that it is questionable whether this germ ever produces pyelitis, except possibly by hematogenic infection.

The medical diseases of the kidneys are considered by Mannaberg in a concise but sufficiently complete manner. Special fullness of detail will be found in the clinical and therapeutic portions of the subject, but theory has not been neglected, as will be seen from a very complete account of the theories of uræmia and the experimental bases thereof. A very conservative view is offered on the surgical treatment of nephritis according to Edebohls (nephropexy) and Israel (nephrotomy), both methods being practically rejected on the ground of insufficient evidence. Mannaberg's criticism of Edebohls' fifty-one cases is that "his successes are unfortunately not sufficiently illustrated by clinical histories," and hints strongly that, "a glance at thoroughly kept histories would be desirable" in the nine cases which Edebohls reported as completely cured.

The section on the surgical diseases of the bladder, by Zuckerkandl comprises 230 pages, and includes 386 bibliographic references. It is thoroughly in keeping with the rest of the book. The last section, on neuroses of the bladder and urethra, by von Frankl-Hochwart, is one of the most interesting in the present volume. Beginning with a thorough treatment of the physiology of urination, the general symptomatology of nervous disturbances of the bladder is considered in detail. A chapter on the disturbances of urination of cerebral origin, with numerous illustrative case histories follows, and the section closes with a summary of the methods of treatment in this class of disorders.

It is gratifying to find throughout the book full credit given to the achievements of American observers. Thus, besides Edebohls, Wagner mentions under nephropexy the work of R. T. Morris, Sturmdorf, Guiteras, Senn, Deaver, and others, and Zuckerkandl gives full credit to the older school, including Bigelow, Otis, and others.

The appearance of the book is similar to that already familiar to us in the principal standard German works. The illustrations are not numerous, but well executed and thoroughly representative. The bibliographies are apparently very complete, so far as the literature of the past ten or twelve years is concerned, but the sources are also indicated where the titles of the older articles may be found, so that the book forms practically an index to the entire literature of urology.

New Inventions.

A GAUZE PACKER.

By FREDERIC GRIFFITH, M. D.

NEW YORK.

To overcome the danger of contamination of a sterile cavity from contact with the surgeon's hands when employing a gauze packer, I have devised an instrument which combines free action of tamponage with perfect protection of the gauze

strip from infection during its progress. The instrument is constructed as follows:

Dr. Griffith's Gauze Packer.

A brass tube three sixteenths of an inch in diameter and twelve inches long is bent and fitted by soldering with ring handles and a small funnel tip, as shown in the figure. A sliding metal bead for use as a guide, as when packing the uterine cavity, is a useful attachment. The projecting wire of steel, one sixteenth of an inch in diameter and ten inches long, is likewise fitted with a ring holder and has its projecting end split for a distance of about one quarter of an inch and the ends sharpened to engage the gauze meshes. In a line with the long axis of the instrument, and at a point at the bend of the tube just behind the grasping part, a hole is to be bored one eighth of an inch in diameter and slotted by filing (to allow the prongs of the projecting wire to be more readily passed). After polishing and nickeling the implement is completed by inserting the projecting wire through the hole in the bend. The mouth of the funnel leading away from the operator's hands, gauze packing or drainage strips need not be handled.

Official News.

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending May 31, 1905:

BAILEY, C. W., Acting Assistant Surgeon. Granted leave of absence for twenty-six days from June 5th.

BIERMAN, C. H., Pharmacist. Granted leave of absence for thirteen days from June 7th.

CARMICHAEL, D. A., Surgeon. Bureau letter of May 24, 1905, granting Surgeon Carmichael leave of absence for fourteen days from May 12, 1905, amended so that said leave shall be for eleven days only.

CORPUS, G. M., Passed Assistant Surgeon. Granted leave of absence for seven days from May 28, 1905, under paragraph 191 of the regulations. Granted extension of leave of absence for twenty-three days from June 4th.

EDWARDS, J. W., Acting Assistant Surgeon. Granted leave of absence for three days from May 20, 1905, under paragraph 210 of the regulations.

GAHN, HENRY, Pharmacist. Relieved from duty at Purveying Depot, New York, and directed to proceed to Washington, D. C., for duty in the Purveying Depot in that city.

HOLT, J. M., Passed Assistant Surgeon. Granted extension of leave of absence, on account of sickness, for one month from May 29th.

MILLER, CHARLES, Pharmacist.—Upon being relieved from duty at the Santa Rosa Quarantine Station, Pensacola, Fla., by Pharmacist W. L. Stearns, to proceed to San Francisco, Cal. and report to the Medical Officer in Command for duty and assignment to quarters.

SCHUG, F. J., Acting Assistant Surgeon. Granted leave of absence for fifteen days from June 15th.

STEARNS, W. L., Pharmacist. Relieved from duty at Purveying Depot, New York, and directed to proceed to Santa Rosa quarantine, Pensacola, Fla. and report to Acting Assistant Surgeon in Charge for duty and assignment to quarters, relieving Pharmacist Charles Miller.

STUART, A. F., Acting Assistant Surgeon. Granted leave of absence for thirty days from July 3rd.

VAUGHAN, G. T., Assistant Surgeon General. Granted leave of absence for one month and fifteen days from June 16th.

WILSON, R. L., Passed Assistant Surgeon. Granted leave of absence for ten days.

Appointment.

Dr. MONTAFIX W. HOUGHTON appointed acting assistant surgeon for duty at Providence, R. I.

Resignation.

Acting Assistant Surgeon J. W. HARGIS, resigned, to take effect May 31, 1905.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended June 3, 1905:

Smallpox—United States.			
Places.	Date.	Cases.	Deaths.
Arkansas—Fort Smith.	Mar. 11-Apr. 22.	8	
Florida—Jacksonville.	May 20-27.	1	
Illinois—Chicago.	May 20-27.	28	
Illinois—Galesburg.	May 20-27.	2	
Louisiana—New Orleans.	May 20-27.	11	
		Two imported.	
Massachusetts—Lowell.	May 20-27.	5	
Massachusetts—Quincy.	May 13-20.	2	
Michigan—Detroit.	May 21-28.	1	
Michigan—Grand Rapids.	May 13-27.	41	
Missouri—St. Joseph.	May 20-27.	12	
Missouri—St. Louis.	May 20-27.	3

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending June 3, 1905:

- ELMORE, B., Assistant Surgeon. Appointed an assistant surgeon in the United States Navy, with the rank of lieutenant, junior grade, from May 24, 1905.
- EYTINGE, E. O. G., Assistant Surgeon. Appointed an assistant surgeon in the United States Navy, with the rank of lieutenant, junior grade, from May 24, 1905.
- GUTHRIE, J. A., Surgeon. Detached from the *Dirie* and ordered to the Naval Hospital, New York, N. Y., for treatment.
- MEARS, J. B., Acting Assistant Surgeon. Ordered to additional duty at the Marine Recruiting Station, Buffalo, N. Y.
- MURPHY, J. F., Assistant Surgeon. Ordered to additional duty on the *Dubuque*.
- OLSON, G. M., Assistant Surgeon. Appointed an assistant surgeon in the United States Navy, with the rank of lieutenant, junior grade, from May 24, 1905.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending June 3, 1905:

- BANISTER, JOHN M., Major and Surgeon. Left Fort Riley, Kan., on leave of absence.
- COLE, CLARENCE L., First Lieutenant and Assistant Surgeon, recently appointed. Ordered to the Bacteriological Laboratory at the Army Medical Museum, Washington D. C., for temporary duty.
- GLENNAN, JAMES D., Major and Surgeon. Left Fort Myer, Va., on ten days' leave of absence.
- HARTNETT, EUGENE H., First Lieutenant and Assistant Surgeon. Relieved from duty at Key West Barracks, Fla., and ordered to Fort Hancock, N. J., for duty.
- JONES, PERCY L., First Lieutenant and Assistant Surgeon. Ordered to report on June 12, 1905, to William H. Arthur, Major and Surgeon, president of examining board, Washington, D. C., for examination to determine his fitness for advancement to rank of captain.
- KOERPER, C. E., First Lieutenant and Assistant Surgeon. Having relinquished leave of absence, ordered to the United States Army General Hospital, Washington Barracks, D. C., for duty.
- MASON, CHARLES F., Major and Surgeon. Appointed a member of a board to meet at West Point, N. Y., about June 5, 1905, for the examination of such officers of the Medical Department as may be ordered before it to determine their fitness for promotion.
- MCCULLOCH, C. C., JR., Major and Surgeon. Appointed a member of a board to meet at West Point, N. Y., for examination to determine his fitness for advancement. Relieved from duty at Fort Hancock, N. J., and ordered to the Presidio of Monterey, Cal., for duty.
- MURTAGH, JOHN A., First Lieutenant and Assistant Surgeon. Granted ten days' leave of absence.
- PERLEY, H. O., Lieutenant Colonel and Deputy Surgeon General. Appointed a member of a board to meet at West Point, N. Y., about June 5, 1905, for the examination of such officers of the Medical Department as may be ordered before it to determine their fitness for promotion.
- RAND, I. W., Captain and Assistant Surgeon. Ordered to accompany detachment Tenth Infantry from Presidio of San Francisco, Cal., to Portland, Ore.
- RENO, WILLIAM W., First Lieutenant and Assistant Surgeon. Ordered to proceed from Fort Myer, Va., to Washington Barracks, D. C., for temporary duty.
- RHODES, THOMAS L., First Lieutenant and Assistant Surgeon. Under orders to report to the president of the examining board at West Point, N. Y., for examination to determine his fitness for advancement.

RICHARDS, R. L., First Lieutenant and Assistant Surgeon. Now at San Francisco, Cal., relieved from further duty in the Philippines Division and ordered to Vancouver Barracks, Washington, for duty.

RICHARDS, ROBERT L., First Lieutenant and Assistant Surgeon. Reported for temporary duty at Fort Mason, Cal.

STILES, HENRY R., Captain and Assistant Surgeon. Ordered to report to William H. Arthur, Major and Surgeon, president of the examining board, Army Medical Museum Building, Washington, D. C., June 15, 1905, for physical examination to determine his fitness for promotion.

STONE, JOHN H., Captain and Assistant Surgeon. Relieved from duty at Fort Leavenworth, Kan., and ordered to Key West Barracks, Fla., for duty.

Births, Marriages, and Deaths.*Married.*

FLETCHER—REDMAN.—In Philadelphia, on Thursday, June 1st, Dr. Benjamin K. Fletcher and Miss Sara Redman.

FORTNEY—FENSLE.—In Washington, D. C., on Tuesday, May 23rd, Dr. Charles Stevens Fortney and Dr. Mary Jeanette Fensler.

HIRST—BOYD.—In Philadelphia, on Thursday, June 1st, Dr. John Cooke Hirst and Miss Maude Wilson Boyd.

LOOK—DONALDSON.—In Kansas City, Missouri, on Wednesday, May 17th, Dr. Henry Harm Look and Miss Mabelle Donaldson.

MERRILL—STARR.—In Cleveland, Ohio, on Wednesday, May 3rd, Dr. Charles H. Merrill and Miss Zorat M. Starr, daughter of Dr. G. F. Starr.

WEIL—STRAUS.—In Long Branch, New Jersey, on Tuesday, May 30th, Dr. Richard Weil and Miss Minnie Straus.

Died.

BURNHAM.—In Chicago, on Sunday, May 28th, Dr. S. B. Burnham, in the eighty-fifth year of his age.

CRESSEY.—In Boston, Massachusetts, on Sunday, May 28th, Dr. Everett L. Cressey.

DROWN.—In Malden, Massachusetts, on Thursday, May 25th, Dr. Edward Payson Drown, in the fortieth year of his age.

MCCNEELY.—In Sidney, New South Wales, on Tuesday, May 16th, Dr. Hugh McNeely.

SMITH.—In Bath, N. Y., on Friday, May 26th, Dr. Ira P. Smith, in the seventieth year of his age.

SMITHWICK.—In Sharon, Massachusetts, on Sunday, May 21st, Dr. John Smithwick.

STEARNS.—In Hartford, Connecticut, on Saturday, May 27th, Dr. Henry P. Stearns, in the seventy-eighth year of his age.

STEELE.—In New York, on Saturday, May 27th, Dr. Thomas F. Steele, in the thirty-sixth year of his age.

SWIFT.—In Pittsfield, Massachusetts, on Thursday, June 1st, Dr. Lawrence C. Swift, in the fifty-fifth year of his age.

TIMS.—In Mt. Vernon, Ohio, on Tuesday, May 23rd, Dr. J. H. Tims, in the eighty-eighth year of his age.

WHITCOMB.—In Liberty, N. Y., on Sunday, May 21st, Dr. J. L. C. Whitcomb, in the forty-third year of his age.

Miscellany.

Chemical Examination of the Urine.—The *Lancet-Clinic*, for April 22, 1905, says: The late Dr. Frederick Kebler used to say that the more he studied diseases of the kidneys, the less he knew about them, and probably all clinicians will admit that their experience, as time goes on, co-

incides with the seeming paradox of this acute observer. Possibly this is because, in that examination of the urine has become almost a matter of routine procedure in a medical case, or at least should be, we have come to rely too closely upon its findings, often to the exclusion of more important clinical symptoms referable to other parts of the body. Indeed, we rather expect the urinary analyst to submit to us an exact diagnosis of the condition of the kidneys without any knowledge as to the history of the case or the symptoms derived by physical examination. On the contrary, however, the expert clinician often finds himself woefully at sea even with the complete report of the urine at hand, as shown by the variance between his clinical diagnosis and that of the autopsy room and pathological laboratory.

Cabot has recently called attention to this variation in a splendidly written article based on the ante and post mortem findings of more than two hundred cases at the Massachusetts General Hospital since 1893. He found that in the so called acute glomerular nephritis, a correct clinical diagnosis was the exception, 75 per cent. being wrong; in subacute glomerular nephritis, 50 per cent.; in chronic glomerular nephritis, 11 per cent.; in chronic interstitial nephritis, 32 per cent.; and in amyloid disease, 100 per cent.; this surprising discrepancy, let it be borne in mind, with full clinical and urinary reports in the diagnostician's hands. In quite a series of cases there was found in the urine at least one quarter of 1 per cent. of albumin, together with casts of all varieties in large numbers, without any discoverable lesions post mortem. When, in addition to this, there is a series without albumin and without casts, or with the latter in very small numbers, yet the gravest of pathological conditions found at the autopsy, we are very much inclined to doubt just how much of these microscopical and chemical changes, when nephritis is present, are due to the nephritis. As Cabot has well said, we may state with propriety that they may depend upon accompanying functional disturbances whose anatomical basis is still unknown and not to the known anatomical lesions which they happen to accompany. The fact of the matter is that a large proportion of physicians are apt to jump to the conclusion, and life insurance companies urge them on, that albuminuria means Bright's, while the absence of albuminuria is proof positive that the individual is not suffering from nephritis, both of which conclusions are erroneous. Albuminuria and nephritis can each appear without the other; for instance, in that chronic progressive disease of the kidney, in which destructive anatomical lesions are present beyond the possibility of improvement, how common it is to see the albumin appear and disappear without discoverable cause; or, on the other hand, after prolonged and severe exercise, as after a boat race, to find the urine of every member of the crew containing albumin in greater or less proportion. Yet in the former example the lesion is progressive and destructive, while in the latter, while the albumin may be in large amounts, the

tendency is toward prompt and complete recovery.

Another old time favorite method of examination which Cabot has the courage to condemn is the estimation of the amount of urea. It is impossible to compute the time lost daily by the thousands of devotees of this rather useless procedure. Its advocates appear to forget that the amount of urea appearing in the urine depends not only, or, indeed, even primarily, upon the functional activity of the kidney, but on the amount of nitrogen taken up by the individual and the catabolism of the entire economy as well. We must know the amount of nitrogen in the food supply of the individual, his power of digestion, and there must also be reckoned with the amount of exercise, sleep, amount of water ingested, presence or absence of fever, vomiting, diarrhoea, cachexia, or heart disease, and any great variation in these factors will completely invalidate the urea estimation. As regards casts, we now know that those of the hyaline and granular variety may be found in small numbers in the urine of healthy adults, while Shattuck has claimed that two thirds of all healthy individuals over fifty years of age show on uranalysis a slight amount of albumin and a few hyaline and granular casts.

It would seem from Cabot's studies that all the time honored methods of examining the urine must be relegated to the background as unworthy of credence, or at least unworthy of the reliance formerly accredited them, and in this all of us who have given the subject any attention must reluctantly coincide. It is simply a trend of the times, a swing of the pendulum for the over enthusiasm of yesterday. It is a warning, of which we have had many of late, that we must not develop and rely upon laboratory diagnoses to the exclusion of those formed by the cultivation of the more simple methods of physical examination. We do not decry any scientific laboratory methods, nor should the laboratory worker regard cynically the phenomena elicited by careful physical examination. The wise diagnostician will take account of both and give to neither no more than its just due.

Local Analgesia.—Captain J. W. Houghton, in the *Journal of the Royal Army Medical Corps*, for April, 1905, states that in view of the growing timidity in the use of general anæsthesia for operations, and the magnification of the functions of the anæsthetist, a few remarks on a method of local analgesia may be of interest. Although cocaine and the various freezing mixtures have been found useful to obviate pain in minor operations, yet their uses are restricted and utility limited. The local analgesia which has recently been brought to the notice of surgeons in England by Mr. A. E. Barker, of University College Hospital, is produced by B. eucaïne, a chemical compound, occurring as a white crystalline powder of low toxicity and readily soluble in water. The injection of this in dilute solution, beneath the epidermis, causes complete analgesia of the parts infiltrated, which effect lasts about twenty minutes. To lengthen the analgetic effect of the B. eucaïne and to obviate the local swelling caused

by the infiltration, a solution of adrenalin chloride can be added, which actively contracts the arterioles, limiting the blood supply, and retains the B. eucaïne in position, increasing the duration of its analgetic effects. The necessity for injecting a fluid isotonic with the blood should not be forgotten, or disaster will occur in otherwise promising cases.

A 1 to 500 solution of B. eucaïne gives a most satisfactory analgesia, and as one seldom or never requires more than 100 cubic centimetres for one operation (usually 10 to 30 c.c. suffice), powders containing B. eucaïne 0.2 gramme (or 3 grains), and pure sodium chloride 0.8 gramme (or 12 grains) can be kept made up. One hundred cubic centimetres of distilled water (about $3\frac{1}{2}$ ounces) are boiled; a stock powder added, and we get a sterile and isotonic solution of B. eucaïne, 1 in 500 normal solution. To this, when cool, should be added 1 cubic centimetre (about 18 drops) of adrenalin chloride (1 in 1,000), which has the desired effect of contracting the local vessels. A point worth mentioning about the adrenalin chloride is its spoiling by exposure to light and air, and its giving a salmon pink color to the solution on standing. But I have kept a solution without deterioration of its contents, for six months. There is no advantage in making up more of the solution than is immediately required, as it loses its properties and is almost inert after twenty-four hours, while its maximum effect is reached thirty minutes after infiltration. To facilitate injection a good hypodermic syringe is essential, and one that can be boiled is an advantage, as the B. eucaïne before the addition of the adrenalin chloride can be boiled without hurt.

I made a small beginning to master the technics of the process, circumcisions and ingrowing toe nails supplying material, and early found the necessity for isotonic solutions and the importance of infiltrating the nerves supplying the area of operation. If one can infiltrate the nerves (say at the sides of a finger), one gets complete analgesia below the point of infiltration, while there is no local swelling to obliterate anatomical landmarks. I have lately used B. eucaïne and adrenalin in the following cases: (1) Removal of a cystic tumor attached to the periosteum of the scalp. (2) Removal of a fibroma attached to the posterior aspect of left trochanter, involving dissection from the bone. (3) Opening a knee joint for removal of loose cartilage. (4) Excision of five varicose veins. (5) Excision and ligature of external piles in a case where chloroform was inadmissible. (6) Opening and draining abscess of liver. (7) Varicocele. (8) Laparotomy for perforating enteric ulcer. In all of these operations the patients expressed their freedom from all pain, except the one with the scalp tumor, which I think was insufficiently infiltrated, while a most peculiar feature of several cases was the fact that though analgesia was complete, total anaesthesia was not present, for on questioning the patients they replied that they felt no pain, but some knew when the knife was cutting them.

The knee joint case was most instructive in demonstrating the effect of the drug, as the pa-

tient had suffered for two years from his joint "locking" on awkward occasions, and was neurotic to a degree; yet I cut down, opened the capsule, removed a piece of detached cartilage, and tapped the surface of the tibia with the point of a knife, questioning him as I worked, and all he said he could feel was a "kind of dull sensation" while I was cutting, but "no pain of any kind." The wound was healed, and the superficial stitches removed on the eighth day.

The laparotomy for enteric perforating ulcer was doubly interesting, as the patient, who had recently come from South Africa, had a very severe septicæmia. Perforation occurred in the fifth week of the disease, with none of the classical signs of perforation, except that he vomited once. When placed on the operating table about six hours after the ulcer ruptured he was pale and collapsed. Temperature 104° F., pulse 144, with scarcely any abdominal distention; in fact, the perforation seemed hardly to aggravate his very toxic condition of the few preceding days. After injecting the B. eucaïne and adrenalin, Captain Humphry assisting, I opened the abdomen in the middle line below the umbilicus; the patient gave expression to slight pain when I pulled on the omentum, which was adherent to the parietal peritonæum in the right iliac region, and out of the infiltration area. The perforation was soon found and closed, his lower abdomen irrigated, the abdominal walls sutured, and a gauze drain left in.

The patient only lived for fifteen hours after the operation, but I think would have died from the intensity of the fever even if he had not perforated. The points of interest were, the absence of pain during operation, the absence of shock, and the marked stimulating effect of the adrenalin.

At the conclusion of the operation, his pulse, which previously was scarcely perceptible, steadied to 106, and his temperature dropped to 101.5° F., while his condition from one of collapse improved so that he spoke intelligently. Such marked changes could scarcely be altogether due to the opening of the abdomen, showing we have in adrenalin a powerful stimulant.

A lack of material has so far limited my experience, but I see no reason why amputations and operations on herniæ could not be performed with this analgetic, the main factor in its successful use being the infiltration of all nerve trunks supplying the site of the operation—not forgetting the probability of nerve anastomosis—while the adrenalin chloride prolonging the analgesia for several hours gives ample time to the operator, and causes an almost bloodless operation. The boiling of the solution ensures sterility, while some preparations are sterile.

As to the question of choice between local and general anaesthesia, the more one sees of local analgesia, in suitable cases, the easier is the choice effected, as the patient escapes the risk and after-effects of chloroform, while the operator is saved the anxiety of its administration, and economy of attendants is effected, as an anaesthetist is unnecessary.

Lectures and Addresses.

THE MODERN DOCTOR.

By A. JACOBI, M. D., LL. D.,

NEW YORK.

(Continued from page 1147.)

Gentlemen, I have seen graduating classes passing before my eyes and out of view these forty-five years. Many of them whom I bade Godspeed have passed away, many have filled their places with success and renown, others have disappeared from sight without leaving their imprint. Still, there are opportunities for everybody. It is true enough that health, circumstances, and luck have a good deal to do with the happenings of whomsoever is mortal. But there is no one who is not to a great extent responsible for his own fate. Selfmade men endowed with principles and endurance are plentiful in every trade and profession. Some rules indigenous with every ethical man should be followed; and, perhaps, it is unnecessary to urge them here. Still, permit me to express in words part of what I should wish you to mind.

You have been undergraduate students until this commencement. Let it be the commencement of your postgraduate study. I take it that you have learned enough to be able to learn more. I once read of the happiness of him who does not know he is no doctor; that happiness should not be yours. Whoever would have stood still with his achievements of forty or fifty years ago would be a hopeless mental corpse. The good doctor of only twenty years ago would be a musty relic to-day if the progress of study and of science had passed him unnoticed. Only constant attention and work will keep you young and abreast of the times. Follow closely the literature of your science and art. Collect a library of your own according to your means. Be sure to take half a dozen medical magazines, one of the great weeklies, a few high grade monthlies and quarterlies, and one historical journal. For, as without the knowledge of the history of your country you cannot understand its structure, or without

that of the embryo the full development of the body, so without that of your science and art you will not be a citizen in your profession. It is a pitiful sight to learn that many efforts are wasted in rediscovering what should have been known. I remember the disappointment our patient and great O'Dwyer experienced when after years of hard work and close thinking he learned that a third of a century previously Bouchut came near to the accomplishment of the intubation of the larynx in membranous croup. It is true that, after all, the world is ringing with his praise, but years were spent by him in unfruitful preparations.

When your private library does not suffice, turn to public collections. Where there is none, create one. There should be no county society without either a circulating or a permanent library. You will always find friends in the Association of American Librarians, and in the large libraries of the country. That of the New York Academy of Medicine alone furnishes much valuable material to several dozen of medical libraries all over the Union.

Try to remain in or improve your contact with all the branches of medicine. There is, it is true, nobody who can know all the various specialties or practise them. Seneca said, 2,000 years ago: "The man who is everywhere is nowhere"—*nusquam est, qui ubique est*—but you should know enough of them to appreciate their relations to the entire organism. Those of you who mean to practise a specialty, I advise to go into general practice first, and build up a specialty in later years on the strength of your general knowledge and attainments. Those who expect to obtain reputation and riches out of premature limitation will not attain success. That such a one cannot reach distinction in his own profession goes without saying; for those specialists who enjoy the confidence and respect of the profession have worked hard and are known for their general and broad information. One cannot impose upon the hearts and purses even of the laymen for any length of time without being found out. The homely saying that you cannot fool all the people

all the time is correct. It may be true that there are many reasons why we should not have a high opinion of the discernment and discretion in matters medical of a large part of the public. For there is too much clairvoyance, Christian lack of science, medical sectarianism, and medicine chest quackery and too much dilettanteism amongst our well clad and well fed seminstructed but uncultured and mentally unbalanced classes. But, if there is any science or art in which the dilettanteism both of the narrow specialist and of the busybody lay adviser is detrimental, it is in medicine. We have been told that a little learning is a dangerous thing. That is a mistake. It is not learning that is dangerous, it is ignorance.

Do not stick to your books alone. They are masterful leaders only when they open your eyes to see the world with. You cannot learn medicine from books alone any better than you can chemistry or politics. Look for bedside experience. Unfortunately, however, there are very few teaching institutions in our country in which clinical instruction is what it should be. Few undergraduates study in schools with hospitals of their own. A mechanic is expected to learn his handicraft before practising; but the medical student is permitted to practise on his fellow men without having the required schooling. That is what gives so much probability to Ughett's story of a Scotch king who would not admit a doctor to his own land until after he had practised at least twenty years amongst his enemies. The lack of clinical experience amongst our young physicians should be more appreciated. Plain talk of this kind may be more wholesome than pleasant. To remedy the evil we want hospitals connected with the schools, not dispensaries only, and large endowments. If rich men and women will spend their wealth for such a purpose they will not so much benefit the medical world as they will benefit millions of fellow creatures. Forty-five years ago the New York Medical College, which is hardly remembered now that it has disappeared these forty years, was the first school to establish a hospital for clinical instruction under its own roof, and this was done out of the contributions of the poor professors and a few friends.

Those of you who follow up your clinical studies in other parts should not believe, however, that the very large clinical hospitals are the most instructive. I think every medical school should have a hospital with selected cases of all kinds containing from 150 to 200 beds. But for the young student or physician to be admitted to large wards, with no personal work and initiative, is almost useless. You learn no botany by star-

ing at a thousand trees and bushes, and no medicine by being driven alongside of hundreds of bedsides. Seeing is not understanding, just as little as the man in practice who, in the course of many years, sees a great many cases with the same indolence, and commits the same mistakes, may speak of from experience. The Siamese twins were carried over fifty thousand miles, but I am sure the only place they knew anything about was their South Carolina village.

Are there particular methods of succeeding in medicine? Books have been written to answer that question. When I read them I wished they did not exist. My advice is, do not rely on any artifice. You see doctors succeed, or not, temporarily or permanently, whether they are ugly, or beautiful, ill mannered or gracious, frowning or, what is worse, eternally smiling, alcoholics or sober, retiring gentlemen or dancing masters and ushers, married or otherwise. Indeed there are those who get married to have an interested attendant on the hall door by day or night; and I have, on the other hand, known unmarried physicians who assured me that they had obtained a large practice by remaining in the market. That sort of advertising which has become an art in modern life is about the most vulgar of all, worse than the newspaper advertising of the downright shameless quack, or the man in more or less of a position who is on good terms with some reporter who visits his clinics—always "without his knowledge"—and is made to extol the skill of the great man, his friend. Even worse are the articles, long or brief, written by metropolitan doctors for advertising sheets called journals, too worthless to serve as soap wrappers.

Then there are the optimists and the pessimists. The man who always gives a good prognosis may do so through good nature and the sympathy he has with the anxiety of the family. His motives are good, but his judgment is not correct. I have suffered from that weakness much more than perhaps my patients, and while I hope you will always try to spare the feelings of those who trust you, you may, by being too soft hearted, cause great disappointment. Do not assure anybody that there is nothing to fear. Any slight ailment may give you the lie; a small opening in a dyke may produce a deluge. That is why I advise you not to think lightly of a possible danger, and not to postpone measures of relief or salvation. An acute disease, particularly an infectious disease, may be like a fire or a tornado. The house may be down before you have called the engine. When you have to deal with a disease that necessarily must exhaust the power of the heart, do not wait

to employ your measures until it is too late. In a pneumonia, one of your daily enemies, you know that every day must and will add to the danger of heart strain and heart muscle deterioration. You have no right to wait for heart failure or exhaustion—any Micawber can do that—if you do, you will generally be too late with your digitalis, caffeine, ammonia, camphor, or musk. Employ them in time. To postpone the use of alcoholic treatment in large doses in septic diphtheria until the tongue is dry and the pulse flies up to 180, is no less than homicide. To rely on nature is indolence. Nature is kind, but nature is cruel as well. The old proverb that the doctor is the servant of nature, if it is to mean that he must fold his hands over his stomach, and look wise and write a certificate of death is a sophism bred by criminal superciliousness. Would you trust nature when a child is suffocating with croup or would you tracheotomize or intubate? When a hernia is strangulated will you permit gangrene to kill your patient? If not, why not open a vein when, on the third day of a pneumonia, there is cyanosis, pulmonary œdema, or dilatation of the right ventricle, and give digitalis and musk in 10 to 15 grain doses?

Then there is the pessimist who either sees or proclaims danger in every mild case. If he sees it he is incompetent. But the suffering public is so ignorant as not to distinguish between a competent and an incompetent practitioner. Still such a man does not *intend* to do harm. But, the clever politician who feeds on the fears of the patient or his friends and exaggerates the danger of the illness and the value of his services, who pretends to save lives by the score when there is no risk—well, just beware of him.

There is another class of politicians, either clever or clumsy, that makes game of what is sacred to many other people, and tries to make a living out of other people's feelings or convictions. I ask you the direct question. Are you to be members of churches? That depends on what the church is to be to you. I knew a medical man whose custom it was to be a regular attendant on all sorts of church funerals, and to have himself called out every time by an urgent message. The attendance being ever so different each time, his name was mentioned in many circles. I know he died poor, however, in spite of, or on account of his silly attempts to obtain notoriety. If you mean to be a member of a congregation, or a deacon, or a Sunday school preacher for similar reasons, I am afraid the shrewd instincts of your neighbors will soon find you out. Otherwise, do not forget that positive religions and creeds do

not necessarily interfere with science, and science does not necessarily interfere with either positive religions, creeds, or churches. The connection with a religious community or the selection of a church depends on accident or individual preference and has nothing to do with your science and art, any more than any other affair of your heart or your political faith. It is not difficult to say that Hippocrates, or Sydenham, or Bichat, or Virchow would not be greater in our estimation if they had belonged to the same religious faith.

Are you to be interested in the politics of the city, the State, the country, or mankind? Alcaïon said more than two thousand years ago: "Man, being a part of all nature, cannot be comprehended without her." I should say, man who is not interested in and feels bound up in his community is incomprehensible. Aristotle called man a political animal, that is, one that felt his intellectual gregariousness and coordination. Take part in honest politics, add your share to the attempts of those who strive to make modern politics honorable again and consistent with the laws of private morals.

Now let me turn to the exigencies of your daily work. In a given case, before everything else make a diagnosis. An architect does not lay a foundation or run up a wall before he has the structure in his mind's eye. So you should be sure of your footing before you go on. Even your most ignorant patient will ask you what it is that ails him, and some of them shake their heads when you talk Greek or Latin to them—and may go to your neighbor who talks in the vernacular. Try to make your diagnosis at your first visit, provided the condition of your patient permits it. This latter is a *conditio sine quâ non*. You have no right to add to the torture or dangers of a fellow creature. It is only nature that is justified and even praised for being cruel; but then, she is only cause and effect, or matter and force, and has no brains and no heart such as you are expected to possess. That is why there are exceptions to the rule of making your diagnosis *first* for, after all, your dealing is more with the organism than with an organ. You are expected to keep your patient alive and save him and not to overlook the man while you study his liver or the exact location of an embolus, and by not adding to his shock you may save his life. Feel his pulse before you use your stethoscope, lower his head when his pallor strikes you, do not insist upon his being bathed according to the rules of your hospital when he has been rattled over miles of pavement before he is put to bed, give him to eat and stimulate him when you have

reason to believe he has had nothing all day before he came to you, and then go to him only with your instruments of precision. The best instrument of precision after all—please remember—is that which you carry in your skulls. It is your brain that should direct your hearts, as it is your heart that should warm your brain.

These two instruments of ours, viz.: brain and heart, are our best guides after all. When you have made your diagnosis be satisfied for a while. The general condition of the patient will teach you your duty from day to day, from hour to hour, no matter whether the pneumonia has invaded another cubic inch of the lung or not. There is such a thing as to be too accurate. When you once have made the diagnosis of a pneumonia and have localized it, and have, perhaps, added the examination of the blood and know all about your patient's hæmoglobin and the number and character of his leucocytes you will find it easy enough to learn the condition of the heart and the kidneys, and build your prognosis on a fairly sound basis. You will impair it by examining too often. Give your patient rest. Do not allow the nurse to insert the thermometer every two hours except for the very best reasons. Know how to leave him alone and keep him alive while his heart, blood, and nerves are engaged in supplying him with oxygen and eliminating his toxins. Spend your wits on sustaining him and facilitating his circulation by hygienic and drug medication and *allow* him to get well. All the rest is experimentation, and man is not *animal vile* on which experiments, even proper and otherwise justifiable, should be made. Imagine yourself in his place and him in yours, and do not spoil his chances and yours by interfering with recovery. Otherwise it may happen what every one of you knew so well twenty years ago, viz., that:

"All the king's horses and all the king's men,
Could not put Humpty Dumpty together again."

Still, I say, make your diagnosis. You have so many more methods of getting at it than we had twenty and thirty and fifty years ago, that it has become, as it were, a natural inference on the part of a young man, just through his examinations for a hospital appointment, to believe that his superior officer might as well resign at once in his favor. The sobering influence of the failures of the approaching lean seven years has not been felt yet. When he will have been in practice fifty years, the young man will learn that there are others who know as much as he or a great deal more. But, after all, the *young men* do make better diagnoses than those made when your fathers were about to be born. That was a time when the

diagnoses of paralysis, of dropsy, of chest disease, of nervous and bilious fever was legitimate and full fledged, when there was no difference between typhus and typhoid, when there was a display of great satisfaction at being able to speak of the rheumatic, the uric acid, and other diatheses, of lithæmia—but I had better stop, for I am on dangerous ground. For the rheumatic and the uric acid diatheses still rule in the supercilious consciousness of those who are not so wise as we the six hundred were. You know that when there is uric acid in the renal secretion, as there ought to be and is, you have the malefactor and go for it; when there is none, and the specific gravity is down to 1,000, so much the worse; the malefactor hides itself in the interior and the poor mortal is drugged at the expense of his (mostly her) health and purse. Still, I say, make your diagnosis in the new ways, but also in the old ways; and do not sham. When stethoscopes were not in everybody's pocket, fifty years ago, I had a colleague in New York, who purchased one of the straight German style and outshone us all by having it ornamented with gold. I have been reminded of him when I see some of the modern "leeches"—you know that doctors in King Edward's time were called leeches—going about armed with the Thoma Zeiss's blood counter and Fleischl's hæmoglobinometer in their satchels. The eye, accustomed to the study of the features, the pupil, and the color and condition of the hair, the color, wrinkling, and veins of the face and hands, the sense of touch developed to the utmost to judge of the character of the pulse, of the condition and size of the viscera, the estimation of the expression of anxiety or terror, or indolence of the sufferer, of the position he assumes, of the dryness or fissures of his lips, of the temperature of his feet; all these also should be carried by the carrier of the satchel, but too often they are not ready for immediate use. I took the liberty many years ago, to assert that brains were a handy tool for a physician. I am wiser now; being so much older, I now say *practised* brains.

Practised brains will easily overcome a difficulty which is encountered in the latest overdevelopment of specialism in medicine. The last few years have evolved a new variety of medical diagnostician, the so called laboratory man. He sits at a certain window—northern exposure preferred—all day long and examines specimens; the bedside knows him not, nor he the bedside.

That I do not speak of the great men of the laboratories, of the Theobald Smiths, of the Ehrlichs, is understood. Medicine is built up of millions of stones, some of little account, some cor-

nerstones, and we exist on serious pathfinding research. You understand me at once when I say that the attempt to discriminate between the laboratory man and the clinician is wanton. The laboratory is in the service of the bedside, a handmaid, available or indispensable according to the circumstances of the clinician, is no less, and need be no more. The individual clinician may not himself be the omniscient or omnipotent expert, but clinical medicine requires the laboratory as one of its aids. That is why every student should take his course and his examination in bacteriology, physiological chemistry, and clinical microscopy. Every patient that ever applies to you has a right to expect from you all the exact aids and branches of knowledge that make the modern doctor.

Do not rely on tools alone. Before there were our instruments of precision, our sphygmographs and manometers, there were great doctors in many lands. Many of our modern medical discoveries and rediscoveries you may read of in the works of Hippocrates, and many modern instruments were found in Heister, two hundred years ago. Our own time reaches the same story, viz., that clinical observation alone arrives at many conclusions laboriously evolved later by the microscope and by experiment. For instance, before the bacillus of diphtheria was ever thought of, a mere clinician taught that almost every case of localized laryngeal croup was genuine diphtheria, and was contagious, and that many cases of so called amygdalitis belonged to the same class. He also taught that laryngitis with a high temperature was not dangerous, while the localized obstructive croup that ran its course without fever belonged to the dangerous membranous type. It was also known that genuine uncomplicated throat diphtheria ran its course without much glandular swelling and that the most septic cases were often those that did not give rise to any fever. All these things have been proved long since by the findings of bacteriology. Thus theories and explanations will often limp behind the knowledge of facts. They are welcome, however, three times welcome, for science means the comprehending of facts together with their causes and correlations.

(To be concluded.)

Philadelphia Polyclinic.—During May the following work was done at the Polyclinic Hospital: Patients admitted to house, 115; patients discharged, 122; new patients treated in dispensary, 1,981; total visits to dispensary, 9,290; accident ward, 754.

THE ÆTIOLOGY AND DIAGNOSIS OF CHOLELITHIASIS.*

By WILLIAM RUOFF, M. D.,

PHILADELPHIA.

Of all studies none is more promising than that of cholelithiasis. Since Marion Sims suggested that gallstone disease was properly within the sphere of the surgeon, investigation and research have been stimulated to a marked degree, the ultimate results of which have gone far to revolutionize our ideas upon this subject.

It is generally conceded that, owing to its anatomical situation, the gall bladder is peculiarly susceptible to pathological changes. Like the appendix it is a dependent organ with a limited outlet, though connected less directly with the intestine and fortunately at a point where virulent microorganisms are neither so abundant nor so active; so that in considering the ætiology and diagnosis of cholelithiasis, it is essential in a sense to include cholecystitis, since both conditions are so dependent upon each other.

Any one familiar with the ætiology of gallstones can understand that no common ætiological factor can be assigned to all cases of cholelithiasis, but rather that a union of several causes is essential to the production of stone. We know that age plays an important rôle, the vast number of cases occurring between the ages of 40 and 60 years and less commonly between 20 and 40 years, and only in rare instances in children and infants. It is possible that some intractable cases of infantile colic may be due to the passage of gallstone. (1) That women should be more susceptible than men, in the proportion of three or four to one, can be attributed to their form of dress and to pregnancy, both factors inhibiting in their own peculiar manner the flow of bile from the gall bladder.

It is less easy to account for the important rôle that age plays in formation of gallstone. We are all perfectly aware of the diminishing powers of resistance, the degeneration of mucous membranes, the gradual atrophy of the body, besides the atheromatous influences that accompany old age, but it seems unlikely that these factors are of such vital importance in the formation of stone; save only that together with the general loss of body tone the bladder suffers equally, losing its contractile power, thereby favoring a retention of biliary matter.

Another factor may be the diminished resistance of the body fluids to infectious agents. This does not prove that biliary calculi are formed in old age.

* Read before the North Philadelphia County Medical Society, December 31, 1904.

It is just as likely that they are produced at all ages, but the intervening years have favored their actual formation. Rather too much importance has been attached to the influence of body temperament and personal habit, gluttony, excessive indulgence in meats and fats, heredity, and climate.

The influence of diet in the ætiology of gallstone suggests a very alluring hypothesis, which, however, lacks confirmation. Cholelithiasis is relatively as frequent in the obese, in the glutton, and those of well nourished organism as in the wasted and impoverished. Naturally sedentary occupations and constant lack of physical exercise favor the formation of stone. Cardiac changes, with atheroma of the blood vessels, carcinoma of the liver and ducts, nephritis, nephrotosis, enteroptosis, and possibly gatropotosis are all predisposing elements in the formation of gallstone. But these factors are not to be considered as the cause of cholelithiasis; they are but the circumstances and conditions that favor their formation in the gall bladder.

Cholelithiasis consists in the formation of crystalline friable masses, composed of cholesterol, lime, various bile salts, and resins precipitated from the bile and bound together by an albuminous matrix or cement. As a rule gallstones are multiple; sometimes but one large stone exists; then again the number found is incredibly large, as many as 7,802 completely filling the gall bladder, having been reported in one patient (2).

The size of the stone varies, being usually in inverse ratio to the number; that is, the smaller the stone the greater the number and vice versa. For systematic study the following classification of cholelithiasis has been accepted (3).

1. *Pure Cholesterol Stones*.—These are hard, oval or spherical concretions, smooth and pure white or yellowish; about the size of a cherry; crystalline throughout.

2. *Laminated Cholesterol Stones*.—These are generally hard but liable to fissure on exposure and variously colored. They are much like the first variety only laminated on section.

3. *Ordinary Gallstones*.—These stones are of various sizes, shapes, and colors, rarely larger than a cherry and often much smaller. They are faceted, brown, or yellow, and not crystalline in structure.

4. *Mixed Bilirubin-Calcium Stones*.—These are as large as or larger than a cherry, solitary or in groups of two, three, or more. On drying, the outer shell or cover peels off. The nucleus and shell is composed mainly of cholesterol, the remainder of bilirubin-calcium.

5. *The Rarer Forms*.—(a) Amorphous stones resembling pearls; (b) chalk stones; (c) concretions surrounding foreign bodies, such as bacilli, worms (*Distoma hepaticum*), needles, silk, or catgut sutures; (d) casts of bile ducts.

The actual formation of gallstones had been the

subject of controversy for decades, until Naunyn (4) in 1892 showed conclusively that gallstones were composed mainly of cholesterol, a monatomic alcohol, and bilirubin-calcium, the source of which was from the mucosa of the gall bladder, and that certain alterations, such as a subacute inflammation of this mucosa, resulted in a disintegration of its epithelium. These epithelial cells or flakes sooner or later showed decided myelin changes particularly in the region of their nuclei, which escaping from their cells were fused, forming a vitreous structureless mass. This mass was found to be pure cholesterol and a compound of bilirubin-calcium. This friable mass of detritus formed the groundwork of the future stone, and as cholesterol and bilirubin-calcium continued to form by crystallization, the stone grew larger and harder. Perhaps a second form of formation is commoner, i. e., an origin from the sedimentary masses met with in human bile, in which small clumps of pultaceous masses are formed, around which is deposited bilirubin-calcium. This sediment, due to biliary stasis, is caused by some obstruction to the flow of bile, either by loss of muscular tone of its walls, mechanical interference, or, which is more than probable, microbic infection.

Of late bacterial infection has proved to be a promising field, but it is after all secondary to obstruction; for, primarily, infection is impossible without obstruction, since the free flow of bile from the gall bladder washes away infective agents, preventing their accumulation in the hepatic ducts and gall bladder proper and, besides, human bile *per se* is sterile. Bile under normal conditions, too, is so poor in nutrition that colonies of bacteria cannot find food for growth or propagation. It is evident, therefore, that some agent capable of retarding the flow of bile or diminishing its motility, is essential to favor the growth of microorganisms.

There are two channels through which the bile may become infected.

1. Through the medium of the portal circulation.

2. By an ascending infection through the common duct from the duodenum.

It is well known that the bacteria of glanders, cholera, and splenic fever have escaped the destructive function of the liver in their migration through the hepatic circulation, and found lodgment in the gall bladder; how much importance they may have in the ætiology of cholelithiasis is not definitely known. But the frequent presence of *Bacterium coli commune* and the typhoid bacillus in the bile and as a nucleus for stone is strongly suggestive of an ascending infection from the duodenum.

It may be of interest, in passing, to note that during an attack of typhoid fever, the character of the bile changes very materially. It is increased in quantity, watery, dirty brown in color, and contains a large amount of epithelial detritus. The relation of an existing cholecystitis during an attack, with the presence of so much disorganized epithelium suggests a rich source of cholesterolin.

Over 20 per cent. of "operable" patients gave a previous history of typhoid fever. The microorganism was found in all, and in some as late as seven years following the initial attack.

Another striking feature of the bile during typhoid, is its agglutinating reaction to *Bacillus typhosus*. This activity is, however, much less marked than that possessed by blood (5). Strange as it may seem, the injection of virulent microorganisms into the gall bladder does not produce cholelithiasis; the violence of the reacting inflammation, producing a cholecystitis or cholangitis, as the case may be, effectively inhibiting the formation of cholesterolin and bile salts. Attenuated cultures, however, have given positive results. The presence of foreign bodies does not produce lithiasis, they being innocuous, until infected, when they rapidly produce stones.

The microorganisms capable of producing gallstones are the *Bacteria coli commune*, *typhosum*, *Staphylococcus pyogenes aureus*, and *Bacillus subtilis*. The influence of appendicitis, peritonitis, and salpingitis is suggestive. Any inflammation of infective character, no matter how remote from the gall bladder, predisposes to the formation of gallstone (6).

In reviewing the ætiology of cholelithiasis the following conclusions may be accepted (7):

1. The chief characteristics of gallstones, cholesterolin and bilirubin-calcium, are produced by subacute inflammatory changes in the membrana mucosa of the gall bladder, resulting in a disintegration of its epithelium and increased production of mucus.

2. That any agent capable of disturbing the motility of the bile through the ducts favors the introduction of microorganisms.

3. That the injection of virulent microorganisms into the gall bladder, produces only a violent cholecystitis or cholangitis, with negative results.

4. That the injection of attenuated cultures causes no change provided the drainage from the bladder is free.

5. Biliary stasis from the introduction of sterile foreign bodies does not occur; but will if the foreign body is infected.

6. The clumping or agglutinating of *Bacterium typhosum* in the gall bladder, may account for the

occurrence of cholelithiasis following typhoid.

In cholelithiasis we usually find such well defined and characteristic symptoms that the diagnosis is easy and comparatively certain. And yet embarrassing mistakes have been made by the internist as well as the surgeon. There is a certain class of patients afflicted with gallstones who never suffer any discomforts, the presence of the stones being discovered by chance upon autopsy. In such cases the concretions have very likely been slow in forming; never causing any interference or exciting any inflammation. In other cases, gallstones may cause vague symptoms of dyspepsia, or disagreeable sensations in the abdomen or liver; but these symptoms are so transitory and insignificant as to not warrant a definite diagnosis. In a third class of patients gallstones cause severe and at times almost fatal illness. It is this class we most commonly meet.

The attacks are characterized by the occurrence of certain peculiar and distinct paroxysms called biliary colic. This phenomenon is usually preceded by discomfort in the abdomen, slight jaundice with itching of the skin, or, as I have seen, with certain peculiar individual warnings, as lumbago, anorexia, and slight nausea. The attack begins suddenly, with acute cutting pains in the right hypochondrium, spreading over the abdomen to the thorax and often extending to the right shoulder; its point of maximum intensity being at the junction of the lower third and upper two thirds of a line drawn from the umbilicus to the tip of the ninth rib (8). There is usually marked rigidity of the abdominal muscles of the right side. Hepatic and cystic infection contribute to the discomfort of the patient. Vomiting is often persistent and distressing, and is accompanied by fever of low degree, from 101° to 103° . The fever is partly a matter of personal equation and partly dependent on the extent of cystic and hepatic infection. The liver is usually enlarged and tender; the gall bladder is swollen and sensitive and palpable, and the spleen likewise shares in the general disturbance. Jaundice appears in twelve to twenty-four hours after the initial symptoms of pain; it is of variable intensity, commensurate with the size and motility of the stone. The duration of the attack is likewise variable, dependent upon the size and quality of the stone and its freedom of motion through the ducts.

Immediately upon the passage of the stone into the duodenum and intestines there is marked relief from pain, though some local tenderness persists for some time. Jaundice gradually disappears and the fever declines, vomiting ceases, and the normal equilibrium of the patient is again established. Recurring attacks are common. The time intervening

depends upon the ætiological factors governing the individual case.

Nor all cases of cholelithiasis terminate so happily, nor does the above comprise all of the pathology of gallstone disease. Death has occurred from perforation and peritonitis, also from reflex spasm, and from collapse, due to prolonged pain.

In some cases severe purulent cholecystitis or cholangitis are formidable complications, either purulent from the beginning or as a sequel. The danger varies with the nature of the infecting agent and the vulnerability of the infected area. Again in others the stone may become impacted in the cystic duct, the ultimate results of which are dropsy of the gall bladder (which can easily be mistaken for a floating kidney), acute cholecystitis, either catarrhal, suppurative, or phlegmonous, with or without perforation and subsequent peritonitis. Usually the stone becomes lodged in the common duct, or in the ampulla of Vater near the end of the common duct, eventually causing a pressure necrosis with serious disturbance of the surrounding tissues, from ulceration, hæmorrhage, perforation, stricture of the duct, or peritonitis to intestinal obstruction and pancreatic involvement.

It is evident from the symptoms just described that often the diagnosis of cholelithiasis is easy and certain in classical cases, but, where the symptoms are obscure and ambiguous a reasonable doubt must exist. It is therefore a pretty safe rule in cases of severe paroxysmal pain in the hepatic region, attended with jaundice, in a middle aged patient, particularly a woman, to think of gallstones. If there is no jaundice, and sometimes there is none, the character of the pain, localized tenderness, vomiting, and finally the enlarged and palpable gall bladder make the diagnosis reasonably certain.

In a certain proportion of cases the diagnosis of gallstones can only rest upon a suspicion. The symptoms of acute non-calculous cholecystitis are so similar to those of hepatic colic that often an operation only can prove the absence of stone. Compared with gallstone colic the pain of right renal colic is in the lower abdomen, beginning in the lateral posterior lumbar region, radiating to the groin and testicle; there are likewise blood and pus in the urine. In gastralgia the pain begins in the epigastrium, near the middle line. Rarely do we have chill or fever, but frequently a neurotic history. If the pain in the middle abdomen is relieved by pressure or by the expulsion of flatus, enteralgia is a logical conclusion.

In nervous women there may arise a pseudo-biliary colic, precipitated or aggravated by fatigue or anxiety. The liver may be enlarged and even tender, pain may be paroxysmal, but the gall bladder is not swollen. There is no jaundice nor is there

fever, and calculi are absent from the stools. Often the diagnosis is very difficult in cases of severe purulent inflammations originating from gallstones. Where there are localized hepatic tenderness, fever, and rigors, conditions suggesting circumscribed suppuration, the possibility of gallstones being a primarily inciting agent should not be overlooked. An abnormally situated inflamed appendix may cause confusion.

There remains but one pathological sequence of note in cholelithiasis, and that is the development of carcinoma of the gall bladder and ducts. It is an important clinical fact, fully established by experience, that the constant pressure of gallstones produces mechanical and local irritation of the mucosa of the gall bladder and ducts with the subsequent development of carcinoma.

Fifty-second Annual Session of the Medical Society of the State of North Carolina.—The fifty-second annual meeting of the Medical Society of the State of North Carolina convened in Benbow Hall in Greensboro, N. C., on May 23rd. A most delightful and instructive session of three full working days was held, during which time more than fifty papers were read. Four hundred of the eleven hundred and fifty members were present. The entire time of the general meetings of the society was given to the reading and discussion of scientific papers. The following officers were elected for the ensuing year: President, Dr. Edward C. Register, of Charlotte; first vice-president, Dr. L. B. McBrayer, of Asheville; second vice-president, Dr. W. H. H. Cobb, Jr., of Goldsboro; third vice-president, Dr. W. O. Spencer, of Winston; secretary, Dr. J. Howell Way, of Waynesville; treasurer, Dr. G. T. Sikes, of Grissom; orator, Dr. James M. Parrott, of Kinston; essayist, Dr. Thomas S. McMullan, of Hertford; leader of debate, Dr. Samuel D. Booth, of Oxford; members of the house of delegates to the American Medical Association for two years, Dr. J. Howell Way, of Waynesville; Dr. James A. Burroughs, of Asheville. Charlotte, N. C., was selected as the place for holding the 1906 session. Dr. Robert L. Gibbon was elected chairman of the committee of arrangements for 1906.

The Medical Club of Middletown, N. Y., was organized at a supper held on June 9th, and the following officers were elected: President, Dr. W. I. Purdy; vice-president, Dr. T. D. Mills; secretary, Dr. J. L. Hanmer; treasurer, Dr. J. B. Hulett.

CLINICAL EXPERIENCE WITH ANTI-TOXINE, AND THE ADVANTAGES OF LARGE DOSES.*

By LOUIS FISCHER, M. D.,

NEW YORK,

VISITING PHYSICIAN TO THE WILLARD PARKER AND RIVERSIDE HOSPITALS, ETC.

It may seem presumptuous on my part to speak concerning the therapeutic indication or dosage of antitoxine in diphtheria, as the specific effect is too well known to need emphasis. The dose required must still be considered empirical inasmuch as we cannot to-day accurately determine the quantity of toxine in the system.

My object in bringing up this subject is to invite opinions concerning the relative merits of large and small doses on the strength of clinical illustrations and accurate statistics kept by the resident staff of the Willard Parker Hospital.

I am indebted to Dr. Henry L. Lynch, acting resident physician of the hospital, for the preparation of the following statistics and for other valuable information:

The antitoxine used at the Willard Parker Hospital is made under the supervision of Dr. William H. Park, and is known as New York Board of Health serum. The strength is about such that 1 c.c. equals 400 to 500 units; 10 to 20 c.c. being the usual dose.

CASE REPORTS. HOSPITAL SERIES.

KIND ASSISTANCE OF DR. CHARLES J. LARKEY.

CASE 1.—Samuel L., 8,000 units of antitoxine injected upon admission.

fair; local, no exudate visible in throat; nasal exudate; complications, none; bacteriological, nose, throat. There was a serosanguineous discharge from both nostrils. Patient was allowed out of bed October 22nd.

CASE I.—Samuel L., aged 3 years; admitted October 15th; ill three days. General condition, fair; local, exudate on both tonsils; nasal exudate; complications, none; bacteriological, nose, throat. October 18th, given soft diet; throat entirely clear of membrane; October 19th, allowed out of bed.

CASE II.—George P., aged 7½ years; admitted October 15th; ill two days.

General condition, fair; local, no exudate visible in throat; nasal exudate; complications, none; bacteriological, nose, throat. There was a serosanguineous discharge from both nostrils. Patient was allowed out of bed October 22nd.

CASE 2.—George P., nasal diphtheria. Injected 3,000 units of antitoxine on the 15th and 5,000 on the 17th.

CASE III.—John L., age 6 years; admitted September 24th. General condition, poor; local, no exudate in throat; nasal exudate; complication,

CASE 3.—John L., 5,000 units of antitoxine on the 24th, 5,000 on the 25th, and 5,000 on the 27th. Nasal diphtheria.

none; nose, there was a profuse serosanguineous discharge. Discharged October 5th.

CASE IV.—Raphael D., aged 4 years; admitted September 18th; ill three days. General condition, poor; local, no exudate visible; complica-

CASE 4.—Raphael D., laryngeal diphtheria. Intubated soon after admission; 5,000 on September 18th; on the 19th, 4,000 units; on the 21st, 4,000 units; on the 22d, tube removed. Reintubated twenty minutes later. On the 25th tube removed, reintubated one hour later. On the 30th, tube finally removed. On October 3d, allowed out of bed. Note the effect of antitoxine on pulse, temperature, and respiration.

tion, croup; bacteriological, none. Patient discharged October 7th. Number of intubations, three.

CASE 5.—Nathan M. laryngeal diphtheria. Intubated upon admission, October 10th; antitoxine, 6,000 units; 11th, 4,000 units. On the 12th, tube removed. Reintubated twenty minutes later. On the 14th, tube removed. On the 16th, constipation.

CASE V.—Nathan M., 6 years old; admitted October 10th; ill two days. General condition, poor; local, no exudate visible: complication. croup. Discharged October 22nd.

CASE VI.—August 5, 11 years old; admitted to the Willard Parker Hospital September 27, 1904. The glands of the neck were swollen. The throat presented a large yellowish gray pseudomembrane which completely covered the pharynx and tonsils and extended upwards, involving the hard palate. The temperature was 102.6° on admission, pulse 108. This child received 10-

000 units of antitoxine on admission. The temperature on the following day was 101°, pulse 100. The condition of the throat was about the same. She then received 5,000 units, and on the third day another injection of 5,000 units. The membrane commenced to exfoliate on the second day after the injection. On the fourth day the throat showed a general clearing up. The disease was arrested by this dose of antitoxine. No complication ensued. The child made an uninterrupted convalescence and left the hospital about two weeks after admission.

CASE VII.—Nichola V., aged 16 months; admitted October 20, 1904. Diphtheria. Exudate on both tonsils. Croup. Intubated shortly after admission (1 year size rubber tube), October 20th. Admitted 11.50 a. m. Temperature, 101° F.; pulse, 148; respiration, 40. The pulse was good, though of rather low tension. The second sound of the heart was sharply accentuated, especially at the pulmonic orifice. Owing to the croup examination of the lungs was negative. October 21st. Temperature, 103.2°; pulse, 140; respiration, 40. Large, coarse râles were found over both lungs posteriorly, and few fine râles over left apex, where the breathing was high pitched, it being harsh over rest of both lungs. There was no dullness. From this point the temperature, taken every two hours, ran a high course, reaching 105°. It was kept down at about 102.5° by keeping the patient almost continuously in a cold pack.

CASE 6.—Augusta S., pharyngeal and tonsillar exudate. On September 27th, 10,000 units of antitoxine injected; on the 28th, 5,000 units; on the 29th, 5,000. Also received 20 c.c. antistreptococcus serum.

An important point in studying the statistics of the Willard Parker Hospital is to note the fact that this is a city hospital and hence when septic cases, unsuccessful tube cases with diphtheria, or cases complicated by pneumonia are sent in the mortality is visibly increased thereby. If we could deduct those patients who are sent into the hospital, frequently in a moribund condition, and those that die within twenty-four hours after admission, then the statistics would prove the specific value of antitoxine more forcibly. We shall have deaths in diphtheria just as long as we hesitate and postpone the use of antitoxine, or until the required dose has been given.

Intubation statistics from the Municipal Hos-

CASE 7.—Nichola V. On October 20th, antitoxine, 5,000 units; 21st, 5,000; 23d, 5,000 units, and pneumonia developing; 25th, pneumonia extending.

pital. Kindness of Dr. William M. Welch.

The following table shows the results in intubation cases of laryngeal diphtheria treated at the Municipal Hospital, Philadelphia, from 1894 to 1903, inclusive:

According to Dr. J. McCollom the treatment in the Boston City Hospital is begun with an initial dose of 4,000 units of antitoxine, repeated in from four to six hours, depending upon the severity of the attack. If the patient has been ill some time before coming to the hospital and has a large amount of membrane, Dr. McCollom gives an initial dose of 8,000 units, and in some instances 12,000 units. His rule is to give antitoxine until there is a marked improvement in the condition of the patient, commencing disintegration of the diphtheritic membrane, and a diminution of the nasal discharge.

¹ Of those which received antitoxine the death rate was 52.94 per cent.

² 24 per cent. of this number did not receive antitoxine.

LARYNGEAL CROUP; TYPES OF CONSULTATION CASES
SEEN IN NEW YORK.

CASE VIII.—A girl, about 9 years old, had been sick with diphtheria about four days. She was

FIG. 1.

FIGS. 1, 2, and 3.—The case of Nichola Vaccara, aged 16 months; illustrating the development of pneumonia from day to day in a case of fatal diphtheria. October 22d, temperature, 102.8°; pulse, 170; respirations, 60. Auscultation revealed numerous fine rales over both apices, with well marked tubular breathing. There was still no dulness. The tube was removed from the larynx.

under the treatment of Dr. Chapman. An injection of 3,000 antitoxine units was given, and as the symptoms progressed a second injection of 3,000

units, and later a third injection of 2,000 units. The disease made still further progress, and laryngeal stenosis was very marked. Dr. H. Jarecky was called in to intubate. I saw this case at the request of Dr. Jarecky on October 21, 1904. As I believed that insufficient antitoxine had been given I advised another injection of 5,000 units. This case received in all 13,000 units. The condition improved from day to day, the tube was removed, and no complication followed.

CASE IX.—On July 24, 1904, I saw a child in consultation with Dr. A. Hymanson. It had a severe type of diphtheria, with visible exudate on the pharynx and marked laryngeal stenosis. When seen by me the pulse was intermittent and the child was gasping for breath. The prognosis was extremely grave; 3,000 antitoxine units had been injected. The case was intubated by me, stenosis relieved, and I sent the child to the Willard Parker Hospital. Another injection of 5,000 antitoxine units was given on admission. The case progressed favorably, the tube was removed, and the child discharged in healthy condition in about three weeks.

Effect of Antitoxine on the Exudate.—After twenty-four to forty-eight hours there is a distinct exfoliation or disintegration of the membrane. It shrivels up, shrinks, and is thrown off after three to seven days, so that the throat or larynx is quite clean of exudate. Extubation should be guided by this symptom.

Case I had an exudate on both tonsils and also nasal diphtheria. The culture showed the presence of K. L. B. The child was admitted to the hospital on October 15th, and the throat was clear of membrane on October 18th. The same effect on the pseudomembrane which can be observed from day to day in the pharynx or tonsils, takes place in the nose and also in the larynx, and it is for this reason that the intubation period is shorter in many cases.

Effect on the Swollen Glands.—Enlarged cervical glands will perceptibly decrease from day to day, and the same effect which has been described on the membrane is also noted on the glands. As

FIG. 2.

FIG. 3.

a rule the glands are reduced to their normal size in about one week.

Systemic Effect.—A decidedly brighter effect can be seen after the toxæmia has been neutralized. One of the earliest symptoms is a return of the appetite, and the functions of the bowels and kidneys improve. Children are more cheerful and want to play.

Avoidance of Complications.—When the disease is arrested in its incipency we naturally prevent complications. The streptococcus and staphylococcus in many cases permeate the Eustachian tube of the pharynx or the nose and cause otitis media. It is advisable in every case of diphtheria to have an aurist examine the middle ear if the slightest irritation or tenderness of the ear is found. I do not look upon the fever curve as a positive symptom of ear trouble, as we frequently have septic and suppurating processes present without any febrile indication of their presence. The ear should be examined in every case.

Danger of Rhinitis.—When rhinitis exists in a family where diphtheria is found, a culture should be taken and the patient injected with at least 5,000 units before the result of the culture is found. If K. L. B. is reported, another injection of 5,000 units should immediately be given.

(To be concluded.)

OBSERVATIONS ON THE DIAGNOSIS AND TREATMENT OF HERPES ZOSTER.

By DAISY M. ORLEMAN ROBINSON, M. S., M. D.,
NEW YORK.

CLINICAL ASSISTANT IN DERMATOLOGY, NEW YORK POLYCLINIC
MEDICAL SCHOOL AND HOSPITAL.

(Concluded from page 1158.)

TREATMENT.

As already mentioned in this paper the treatment as recommended in text books and in special articles in journals refers almost exclusively to measures for the relief of pain and local applications for the cutaneous lesions; in other words, to a symptomatic treatment without any reference to the prevention of the pain or to a controlling influence on the course of the lesions or disease.

It seems to me that a consideration of the ætiology and nature of the disease and of its normal course and action on the organism are of much importance and value in forming a basis for the intelligent treatment of this disease. Although the older writers were quite familiar with the external appearances of the disease, it may be said that until the time of Bärensprung not much attention was paid to the ætiology or nature of the affection. This author from clinical observation and anatomical studies concluded that the disease was one of inflammation of the intervertebral spinal ganglia or corresponding structures,

without further researches as to the cause of the inflammation of this special structure.

We know now, although these ganglia are almost invariably affected, that a zoster may occur without changes in the ganglia, the changes occurring either in the nerve external to the ganglia or between the ganglia and spinal cord, or in the spinal cord itself. Some writers place it in the same category with spinal paralysis of children—that is, as an acute infectious disease—others have regarded it as a special affection of the nervous system, a pure neuritis, but this latter view has, I think, very few followers at the present time.

A zoster associated with carbonic acid poisoning has been observed. Hutchinson was the first to draw attention to the occurrence of herpes zoster in persons who were taking arsenic for certain skin diseases. The number of these cases in persons taking arsenic reported since that period to the present time is considerable. Nielsen, of Copenhagen, reports that in 777 patients with psoriasis, 557 were treated by arsenic and of these 39 had zoster; of the other 220 not treated by arsenic, there was no zoster. Arsenic was not always given up to the time of the outbreak. In 7 the interval was one month; in one case of these 7 the interval was three and one half months. The eruption in these cases was always that of a classical case of herpes zoster, was most frequent in the usual location, was of the usual course, was unilateral in distribution, and in no case was there a recurrence of the disease as far as is known. Nielsen considered that the eruption should be classed under the head of a drug eruption, but this view can hardly be considered to be correct when we note that the eruption ran its regular course in cases where there was no cessation in the administration of the drug. The absence of a recurrence under the continued use of arsenic is also against such a view. It seems to me fair to suppose in consideration of these facts that the arsenic did not produce the eruption, but that persons taking arsenic are unusually liable to zoster.

A number of cases have been reported in connection with traumatism of the nervous system; and with the disease of the spinal cord in connection with tumors in the neighborhood of the spinal ganglia, etc. Some of these cases at least were not true cases of herpes zoster, but rather to be classed as zosteriform eruptions, or, as I prefer to call them, herpetiform eruptions, although no doubt some of them were cases of pure zoster. A direct relationship, however, between the traumatism and the zoster remains to be shown.

The vast majority of the cases, apart from all of these reported which, after all, are comparatively few in number, that come under observation are, in my opinion, unquestionably examples of a general infectious disease with local manifestations. The fact that the disease occurs in a more or less epidemic form at certain periods of the year, for instance, usually in the fall and spring in New York; that it starts with prodromal symptoms; that it has a period of incubation; that it is accompanied with febrile disturbances to a variable extent in different cases; that the severity of the disease varies in different epidemics; that there is an apparent wave of varying intensity in single epidemics like that occurring in scarlatina, measles, etc.; that the eruption has a definite anatomical distribution; that the lesions follow a definite pathological course and with a more or less definite duration of existence; and that, finally, an apparent condition of immunity is produced, seems to me sufficient evidence that the disease in these cases—the vast majority of all cases observed—is to be considered as the result of microbic infection. That only a portion of the nervous system is the seat of the inflammatory changes—that is, that the local manifestations are limited to a single ganglion and the peripheral nerves in connection with that ganglion, or that two or more ganglia or parts of the nerve ganglia are affected at the same part or in distant parts of the body, need cause no wonder any more than it does in cases of anteriopoliomyelitis. This cannot be used as an argument against the infectious nature of the disease.

The law of difference of vulnerability as regards infection in general in tissues of similar anatomical structure in different parts of the body suffice to explain the different seats of the local manifestations in different cases of zoster—why in one case we have a dorsopectoralis and in another a zoster ophthalmicus, etc.

Some cases of apparent indirect contagion have been reported; for instance, two cases occurring within a short period in persons who had occupied in succession the same room. There were under my care this year husband and wife, both of whom had zoster pectoralis; the wife was the first to have the disease and two weeks after her recovery the eruption appeared upon the husband. While the history does not *prove* a contagious origin in the case of the husband, yet it is favorable circumstantial evidence and as such I have given it.

Admitting then that in a zoster with the prodromal and other symptoms which I have described we have to deal with an acute infectious

disease giving immunity, we have to consider from a therapeutical standpoint, first, the organisms producing the disease; second, the toxins, the result of the life activity of the organisms; third, the local manifestations of the disease, and fourth, the nature of the ground—that is, the physical condition of the individual affected.

One might ask the question, admitting zoster to be an infectious disease, Does a given case demand more than symptomatic treatment? If all cases of general infectious diseases were similar in character as regards the severity of the disease, a fixed rule in treatment could be followed for all cases, but as that is not so, each case must be a law unto itself in addition to the general law or principles of treatment for every case. Many cases of chickenpox, for instance, are so mild that no medication is required in the form of drugs, while other cases are quite severe, especially in adults, and demand particular attention.

It is not for me on this occasion to enter into a consideration of the possible injuries to secretory or other organs of the body, or to tissues from toxins present throughout the system in cases of general infectious disease. It seems to me, however, that this subject has not been sufficiently studied up to the present time; but the broad statement may be laid down that during the active stage of any general infectious disease associated with elevation of temperature, catabolic processes, and injury to tissues, the patient should be treated as if he had a serious disease, at least until it is shown that as a result of the particular disease no permanent injury is ever produced in mild cases to the tissues of the body whether they be the epithelial cells of such organs as the kidneys, etc., or of the nervous system, heart, etc. Whatever influence the peculiar condition of the tissues as the result of processes occurring in them in acquiring the condition of immunity may have as a predisposing factor in the causation of pathological conditions later in life, such as in nephritis or in disease of the heart muscle, etc., is as yet unknown, but it is a subject worthy of thought and study.

Of all the infectious diseases syphilis seems to be the only one up to the present time that has been studied along these lines, and we recognize from the studies and observations in this disease and a recognition of its influence as a predisposing factor in many later pathological conditions, the value of early, continuous, and active treatment in all cases. Certainly what holds true of syphilis must hold true of all general infectious diseases until the contrary is shown. I feel that too much weight cannot be attached to this view

of the remote influence of general infectious diseases upon the subsequent life of the tissue cells of the body.

We have seen in zoster that the disease has the prodromal symptoms already mentioned, that fever conditions exist, that a lymphadenitis, the result of a toxæmia is present, and that occasionally a muscular paralysis occurs. There is also the pain connected with the eruption and the occasional long continued subsequent pains—conditions sufficient for us to consider zoster a serious affection and to be treated on the same principles as we would treat any other general infectious disease.

Admitting that the fever, the lymphangeitis, and the prodromal symptoms depend upon toxins, and that the injury to the nervous system as represented by the pains, the muscular paralysis, and the cutaneous eruption, depend also upon organisms or their toxins, our first object should be the use of agents, if we possess such, to destroy the organisms or inhibit their life action, and thus prevent a toxæmia or restrict the amount of intoxication.

It is probable from the character of the cutaneous eruption that the toxine is a soluble one, and that if the organism was known, possibly an antitoxic agent could be procured on the same lines that the antitoxine has been produced for diphtheria. As we know nothing about the organism, our treatment is necessarily on the broad lines governing any infectious disease, and the use of such drugs as we know to be of value in this particular affection. When I refer to the broad lines of treatment I mean rest of body, proper nourishment, and particular attention to those organs of the body which aid in the removal of toxins from the system, as the skin, kidneys, and intestinal canal, or that destroy them within the system, as the liver.

Arguing from what I think is a general pathological law, that in acute infectious diseases giving the condition of immunity, the fewer toxins formed or the less the intoxication of the system, the less is the injury to the tissues and the earlier does the immunity condition occur. Accepting that statement, it follows that by a lessening of the amount of intoxication, the less will be the injury to the nervous and other systems and the shorter the duration of the disease; also that there will be less pain and fewer muscular paralyses and a milder and shorter inflammatory process in the skin.

How can we reduce the amount of intoxication in cases of zoster? We do not know of any agent given internally that influences the life activity of the organism in the general system; but it is

fair to suppose that the application of cold to the region of the affected ganglion would have such an action on organisms located in that structure. If such an action follows the use of cold, it means that there are fewer toxins formed at that part and hence less injurious inflammatory action in the ganglion tissue. If the inflammation of the ganglion is caused by toxins generated elsewhere, the action of the cold would be limited to its action as a local antiphlogistic agent. We must then consider the effect of such an action on the cutaneous eruption and on the nerves affected. If the cutaneous eruption depends for its extent and severity on the injury to the nerves, it follows that the eruption would be correspondingly influenced. It would be less acute and of shorter duration if the inflammatory action in the ganglion was lessened by any agent, and cold has such an action in local inflammatory processes. A part of this argument is of course merely theory—but I think good theory, as one cannot prove the actual value of cold in a given case. For the reasons mentioned, I believe cold by means of an icebag, for instance, should be applied, for a few days at least, over the ganglia affected.

I have observed that in cases seen early, the administration of a coal tar preparation, such as antipyrin or phenacetin, is of the greatest benefit in the majority of cases—both as regards a lessening of the severity of the symptoms and in diminishing the duration of the disease. How the drug acts, I do not know, perhaps through its own anodyne action on the affected nerves, making them less vulnerable to the poison and hence less injuriously affected and, therefore, influencing the intensity of the cutaneous inflammatory process; or as a pure antitoxic agent, rendering the toxins innocuous to an extent. I am inclined to the latter belief, as the life duration of the cutaneous lesions is usually much lessened. There is such an interference in the normal lesion formation that they may be said to be aborted, many of the papules never reaching the vesicular stage and the vesicles drying up early, with less tendency to the formation of bullæ than usually occurs. This does not occur in all cases, but perhaps it has been the fault of the dosage. In elderly subjects and in those of a neurotic temperament, the failures have been most frequent.

The abortive action is not so reliable if the case is not seen until the eruption is in an advanced stage, hence the importance of early observation and treatment. In this respect it resembles the use of antitoxine in diphtheria. The dose of antipyrin given has been ten grains twice a day for three or four days in cases of adults and in children and in old people the proper corre-

sponding amount. The treatment here recommended is based upon observations made in many cases of the disease.

It is possible that the dose of the coal tar preparation should be increased in the more severe cases or in those cases that do not appear to be quickly influenced by the treatment, especially at the beginning. Future observations may enable me to lay down more definite rules for individual cases.

Although not a believer in the malarial origin of zoster, as in the cases so far in which I have examined the blood, the *Plasmodium malariae* was not found, I have given quinine also, but I am satisfied that the benefit was derived from the coal tar preparation.

When we consider the pain and suffering during an attack of zoster and the serious after results in some cases, the persistent neuralgic pains lasting years and months, we must recognize the value of a treatment that will usually abort the disease, lessen the injury to the tissues, and probably prevent subsequent neuralgia. For the pain, codeine can also be given if necessary, and in neurotic subjects bromide of potassium is often of benefit.

To sum up, the plan of treatment I recommend for herpes zoster is: Rest, attention to the general nutrition of the body, the combating of the microbes, the application of cold over the affected ganglia, a coal tar preparation for the toxæmia, and codeine and bromide of potassium for pain not controlled by the antipyrin. Local treatment consists in aseptic and antiseptic measures. If the case is seen at a very early stage, the affected area can be disinfected in the usual manner by soap and alcohol and then painted with flexible collodion—and when convenient an antiseptic gauze applied. If seen later, when vesicles are changing in color, an ointment of boric acid and bismuth subnitrate, and avoidance of soap and water meet the indications. Later ichthylol can be added to the ointment, or an antiparasitic preparation, as the ammoniated chloride of mercury ointment with rose ointment to which bismuth may be added and also ichthylol.

For the persistent neuralgias following zoster, anodynes and the faradaic current or x ray may be of some curative value, but on account of probable structural changes in the nerves and connective tissue of the ganglia, the condition is very rebellious to usual methods of treatment for neuralgia. Tonics, such as phosphide of zinc, and alteratives, such as arsenic, are also recommended.

I will not mention other methods of treatment

that have been proposed; I have desired to present original observation or experience on the subject and conclude with expressing the hope that you are satisfied that the subject is sufficiently interesting to be worthy of your attention.

159 WEST FORTY-NINTH STREET.

LOCAL VERSUS GENERAL ANÆSTHESIA IN RECTAL SURGERY.*

By JAMES P. TUTTLE, M. D.,

NEW YORK.

The two features which chiefly distinguish modern surgery from that of former periods are anæsthesia and asepsis; upon these depend the comfort and the lives of our patients. There are many methods and means employed to accomplish each of them, and it is the object of such meetings as this to sift the evidence and determine as far as possible which are the best.

The question which we have before us to-night is the comparative merits of local and general anæsthesia as applied to rectal surgery.

The anus and lower rectum are highly endowed with sensory and sympathetic nerves. The reflexes of these organs are more widely distributed and more persistent than those of any other organ in the body. Their sensitiveness is so acute that pain here is more unbearable than at any other part of the body. A small fissure or ulcer which in other places would cause only annoyance, excites a real agony in the rectum. When inflamed or injured the manipulation of these parts is almost unbearable and one of these accounts analgesia and anæsthesia come among the most important problems in rectal surgery.

Analgesia is indicated in painful diseases and postoperative conditions; anæsthesia in examinations and operative procedures. The *analgetics* are topical and constitutional, the *anæsthetics* are local and general.

The chief topical analgetics are anæsthesin, orthoform, cocaine, eucaïne, carbolic acid, sodium bicarbonate, etc. They are applicable in sensitive lesions of the ulcerative or traumatic types. Anæsthesin, orthoform, and carbolic acid are effectual in the relief of pain from pathological lesions such as chronic, tuberculous, syphilitic, and cancerous ulcers. Cocaine and eucaïne while sometimes effectual in these are usually more so in acute lesions. Sodium bicarbonate is analgetic only in burns and is therefore chiefly used for dressing cases operated in with the actual cautery. For this purpose it is incomparable. In examinations of the

* Read before the New York County Medical Society, December 27, 1904.

rectum when there are painful ulcerations or fissures at the margin of the anus, anæsthesin or orthoform well applied to the part will usually relieve the pain to such an extent that general anæsthesia is rarely necessary. In one of the favorite non-operative treatments for fissure, that by small tampons soaked in ichthyol, the pain of the application is greatly reduced by coating the tampon with anæsthesin. Detail is impossible here, but numerous such applications of these topical analgetics render the treatment of painful conditions of the rectum much less distressing than they would be without them.

The effect of these remedies is evanescent, however, and as they cannot be applied by the patient we must often resort to constitutional analgetics. Of these morphine, opium, codeine, antipyrine, phenacetine, acetanilide, chloral, the bromides, and chloretone are the most useful. First of all the pain relievers is opium in its various forms, but aside from its dangers and the possibility of inducing "the habit," it is often undesirable in rectal diseases on account of its constipating effect. And, again, as much of the pain in the rectum is due to spasm of the sphincter it often requires unsafe doses of opiates to relieve this. In such cases chloral and the bromides are more effective and safer remedies.

In chronic aching or neuralgic pains of the rectum a combination of antipyrine and acetanilide, with a small quantity of codeine (one eighth of a grain), is often more effective than opium and should be used in preference. Personally I am very chary of the use of cocaine and opiates as analgetics in rectal disease, for I have seen many habitués from this class of patients. The other remedies mentioned seem to be without any such danger and they are quite satisfactory in the relief of pain.

The chief local anæsthetics are carbolic acid, ice, ethyl chloride (locally applied), cocaine, eucaine, stovaine, and sterile water injected hypodermically into the parts.

The first three are satisfactory only in very minor operations, such as superficial thrombotic hæmorrhoids, herpetic cysts, and abscesses very near the surface; of them, carbolic acid is the best. A small streak of pure acid over a superficial thrombotic hæmorrhoid or abscess often enables us to incise it almost painlessly. It always enables us to introduce the hypodermic needle for the introduction of anæsthetic solutions without pain, at the same time disinfects the skin through which the needle must pass, thus lessening the danger of infection. I have had little satisfaction from the freezing processes either by ice or ethyl chloride in rectal operations.

Where incisions of any depth or magnitude are

to be made and local anæsthesia is to be employed, the hypodermic method should be selected. Experience teaches us that the chief pain in inducing anæsthesia by hypodermics in tender parts is produced by the distention of the parts by the injected fluid; especially is this true if the carbolic acid is used to prevent the pain from the prick of the needle. It may be stated as an axiom therefore that, *other things being equal the substance which produces the greatest anæsthesia per minim injected into the parts will be the most satisfactory.* If this is true, then cocaine, eucaine, or stovaine should be the remedy of choice. Almost complete anæsthesia for minor operations can be produced by the injection of a few drops of a one per cent. solution of any one of these drugs in the majority of cases, and as there is very little distention the pain of introduction is consequently slight. By the proper use of these injections hæmorrhoids may be ligated or excised, small fistulas laid open, and fissures incised with comparatively little pain; so little that timid patients stand it rather than take ether or even gas—but always there is enough sensation to cause more or less restlessness, anxiety, and shrinking from the operator and consequent interference with the very best work in difficult cases. I have occasionally stretched the sphincter under local anæsthesia, but it has always been attended by considerable pain. On account of this one distinguished operator cuts the muscle instead of stretching it—a procedure which conservative surgeons will not endorse.

An objection commonly made to the use of these drugs is the danger of their constitutional effects. Hundreds of experiences in the use of cocaine and eucaine make me believe that this objection is chimerical. Occasionally I have seen the temporary exciting or depressing effect of cocaine follow its hypodermic use in operations, but I have never seen any dangerous manifestations and I do not believe they occur unless large quantities or strong solutions are used—one per cent. is as strong as is ever necessary and one quarter of this strength is usually sufficient.

But local anæsthesia can be produced by distending the tissues until they are blanched by the hypodermic injection of simple water, and by this means one can avoid the constitutional effects altogether. In properly selected patients it is possible by this means to do almost all minor operations in rectal surgery. There are some serious objections to this method.

1st. The distention itself is quite painful.

2d. The frequent punctures through tissues which can hardly be sterilized invites infection.

3d. These punctures and the distention may rupture deep blood vessels, cause extravasation, and

so interfere with the circulation as to cause subsequent sloughing of the perirectal tissues.

4th. The distention so disturbs the parts that one is unable to tell just how much tissue ought to be removed.

5th. It is not absolutely reliable. At least half of the patients in whom I have tried it twisted and squirmed about until it was impossible to complete the work satisfactorily.

There are two objections applicable to this and to all forms of local anæsthesia—viz., if one gets outside of the anæsthetized area there is great pain and one must stop to do more injecting, thus interrupting the work; and again, however little actual pain the patient may suffer he is always restless and alert to appreciate any accident or complication that may arise during the operation and thus interfere with its thorough completion. Another serious objection to local anæsthesia is that it inclines both the surgeon and patient to underestimate the operation and to neglect proper preparation, the aseptic technique, and the advantages of rest in bed after all operations on the rectum.

In spite of these objections local anæsthesia has its field of usefulness in rectal diseases. Its chief advantages are that it enables us to do work in the office that would otherwise have to be done in the hospital or at home; it occasionally allows us to operate in cases where ether or chloroform is contraindicated, and lastly, though first in the minds of those to whom a large and lucrative practice are the first objects of a professional career, it brings to us many patients who are afraid of general anæsthesia and refuse to be operated upon if it is to be used. Of this latter class of patients it may be said, these "cowards die a thousand deaths from fear." The pain of operation with local anæsthesia under the most favorable circumstances is manyfold greater than that with general anæsthesia and the after pains are no less, but many prefer to suffer thus, and when the operation is over congratulate themselves on not having taken ether. Much may be said in the excuse of such sentiments in those who have seen the old barbarous methods of giving ether—where three or four strong men held the patient down while the anæsthetic was forced on him. But these methods are obsolete and, thanks to ethyl chloride and nitrous oxide gas, such distressing scenes are no longer witnessed. By the preliminary use of these drugs the patients go into ether anæsthesia as into quiet sleep and suffer very little from succeeding nausea. There is absolutely no pain during the operation and the surgeon is not hampered in his work by the twitching and squirming of restless, anxious patients. In the majority of cases rectal operations can be completed under the ethyl chloride or gas

without ether, as the procedures require but little time.

For hæmorrhoids, small fistulas, and fissures it is my practice to cleanse the parts, place the patient in the lithotomy position, and then administer the ethyl chloride or gas, and usually the operation can be completed without resorting to the ether. Especially is this true if the patient is given a hypodermic of morphine five or ten minutes before the anæsthesia is begun.

I prefer the ethyl chloride because it does not produce cyanosis like gas, and the apparatus for administration is much less complicated. We employ the drop method introduced by Dr. Lynch and use an ordinary chloroform mask. For minor operations such as one is justified in doing in the office, we employ it almost daily and allow the patient to walk home half an hour afterward. In children it is the ideal anæsthetic in rectal diseases and we have seen no ill effects from it in child or adult. With it one can do absolutely without pain any operation justifiable in office practice, and do it thoroughly unhampered by the restlessness of conscious patients. The one objection to it is it does not relax the muscles completely as does ether, and for this reason the patient must be put in the lithotomy position before the ethyl chloride is begun. I do not mean by this to endorse indiscriminate operations for rectal disorders in one's office. In the large majority of cases this is unjustifiable, but when not so, ethyl chloride seems to me to be the most satisfactory and reliable anæsthetic. After all is said ether is the most satisfactory anæsthetic in extensive or prolonged operations about the rectum. The complete relief of pain, the perfect muscular relaxation, the regular breathing, the absolute quiet of the patient, all contribute to the execution of perfect surgical work and the subsequent comfort of the patient.

Chloroform also has its advantages and disadvantages, but as these are the same in rectal as in general surgery they need not be mentioned here. But one thing needs to be said: In all operations upon the rectum with whatever anæsthesia, we should always bear in mind the intimate reflex connections of this organ with the pneumogastric nerve. Sir William McEwen has laid great stress upon this, saying:

"The reflexes arising from impressions on the peripheral distribution of the pudic and associated nerves persist while the patient is under the influence of the anæsthetic.

"In many patients deep general anæsthesia greatly modifies, though it does not altogether inhibit this pudic reflex, but in others the placing of the patient as deeply under the influence of the anæsthetic as is consistent with safety has no ap-

parent inhibitory effect. It has been observed that when any prior obstruction to respiration existed, such as to induce venosity of the blood, the respiratory centre becomes more easily affected by the pudic afferent impulses; while under the anæsthetic the pudic afferent impulse produces no response in the lumbar reflex centre, the anæsthetic seeming to have inhibited its action. On the other hand, the pudic peripheral impression produces an instantaneous response from the respiratory centre, inducing generally a prolonged tetanic inspiratory gasp, and sometimes a deep stridulous inspiratory effort each time the peripheral impression is repeated. Though the heart participates in this reflex through the vagus, the effect upon it is seldom the prominent feature, and in the majority is so slight as to be either imperceptible or to pass unnoticed by the finger of the assistant on the pulse. . . . In the neurotic the cardiac effect is more pronounced. . . . All these reflex phenomena occasioned by stimulation of the pudic nerve may be prevented or greatly lessened by local anæsthesia, induced shortly before the administration of the general anæsthetic. For small operations local anæsthesia alone might suffice, but in the majority of instances the combination of local with general anæsthesia is safer, as the reflex is more completely controlled."

It is for these reasons that we have found a hypodermic of morphine preliminary to the administration of general anæsthetics so satisfactory in rectal surgery.

To summarize: Simple fissures, small straight uncomplicated fistulas, ordinary skin tabs, isolated, prolapsing internal hæmorrhoids in patients with stable nervous organisms may all be satisfactorily operated on with local anæsthetics, of which cocaine and eucaine are the best. In all other conditions, including extensive hæmorrhoids, complicated fissures and fistulas, and always in neurotic hyperæsthetic individuals we should resort to general anæsthesia.

The Wisconsin Medical Union of Physicians and Surgeons has elected the following officers for the ensuing year: President, Dr. James L. Barber, of Collins; first vice-president, Dr. T. E. Williams, of Eau Claire; second vice-president, Dr. Nils Hanson, of Superior; recording secretary, Dr. F. X. Schaeffer, of Milwaukee; corresponding secretary, Dr. F. L. Mehrtens, of Milwaukee; treasurer, Dr. R. B. Hansen, of Oshkosh.

Medico-Chirurgical Society of Central New York.—Officers of this society have been elected as follows: President, Dr. A. R. Grant, of Utica; vice-president, Dr. A. M. Willer, of Lafayette; second vice-president, Dr. E. A. Simmons, of Carthage; secretary and treasurer, Dr. Ellis M. Santee, of Cortland.

FIBROID TUMORS OF THE UTERUS; THEIR SURGICAL TREATMENT.

By FRANKLIN H. MARTIN, M. D.,

CHICAGO,

PROFESSOR OF GYNÆCOLOGY, POSTGRADUATE MEDICAL SCHOOL.

I base the conclusions arrived at in this paper (1) on the analysis of the last two hundred consecutive cases of fibroids of the uterus operated upon by me by hysterectomy or myomectomy up to December 1, 1904; (2) on the analysis of 1,188 cases reported by Dr. Charles P. Noble before the American Gynæcological Society, May 26, 1904, and, (3) on knowledge gained by the different forms of less radical operative procedures and on the non-operative methods of treatment employed by myself during a period of over eighteen years in caring for more than four hundred cases not submitted to radical operation.

1. The complications of which I have records in the 200 cases recently operated in, may be divided into (a) those arising in the tumor itself, and (b) those arising as accessory complications to the growth.

a. (1). Among the inherent conditions giving rise to dangerous symptoms among the 200 cases may be enumerated (1) enormous development of growth rendering operative interference imperative, which occurred in 11 cases, or 5.5 per cent.; (2) dangerous uncontrollable hæmorrhage in 41 of the cases, or 20.5 per cent.; (3) pregnancy complicating the tumor, making operation necessary, in 6 cases, or 3 per cent.; (4) carcinoma of the cervix in 2 cases, or 1 per cent.

(2) The following inherent conditions of importance were discovered when the tumors were removed: (1) Serious broad ligament extension in 19 cases, or 9.5 per cent.; (2) serious adhesions to soft parts in 8 cases, or 4 per cent.; (3) cystic degeneration of the tumor in 8 cases, or 4 per cent.; (4) myxomatous degeneration in 30 cases, or 14 per cent.; (5) calcareous infiltration of the tumor in 6 cases, or 3 per cent.; (6) deep suppuration of the tumor in 2 cases, or 1 per cent.; (7) carcinoma of the body of the uterus complicating the tumor in 3 cases, or 1.5 per cent.; (8) sarcoma complicating the tumor in 2 cases, or 1 per cent.; (9) senile endometritis giving rise to severe symptoms after the menopause occurred in 3 cases, or 1.5 per cent.; (10) suppurative endometritis was a complication in 5 cases, or 2.5 per cent.; (11) submucous projection of fibroid centres which produced serious symptoms occurred in 11 cases, or 5.5 per cent.; (12) necrosis of the centre of the tumor occurred in 3 cases, or in 1.5 per cent.

b. Accessory conditions depending on or complicating the fibroids were the following: (1) Pyo-

salpinx (double) in 20 cases, or 10 per cent.; (2) pyosalpinx (single) in 5 cases, or 2.5 per cent.; (3) hydrosalpinx in 6 cases, or 3 per cent.; (4) cystic ovaries (double) in 7 cases, or 3.5 per cent.; (5) malignant adenocystoma of the ovaries in 1 case, or 0.5 per cent.; (6) parovarian cysts in 5 cases, or 2.5 per cent.; (7) dermoid cysts of the ovary in 5 cases, or 2.5 per cent.; (8) large adenocystomas in 7 cases, or 3.5 per cent.; (9) hæmatoma in the left broad ligament in 4 cases, and in the right broad ligament in 3 cases, making a total of 7 cases, or 3.5 per cent.; (10) varicose veins in the broad ligaments in 5 cases, or 2.5 per cent.; (11) extensive intestinal adhesions in 8 cases, or 4 per cent.; serious and chronic intestinal obstruction from tumor pressure in 7 cases, or 3.5 per cent.; (13) acute intestinal obstruction from pressure in 2 cases, or 1 per cent.; (14) serious pressure symptoms in 13 cases, or 7.5 per cent.; (15) appendicitis in 6 cases, or 3 per cent.; (16) extrauterine pregnancy in 2 cases, or 1 per cent.; (17) pregnancy complicating large sub-peritoneal fibroids, in which tumors were removed and pregnancies allowed to go to term, 3 cases, or 1.5 per cent.; (18) tuberculous peritonitis complicating the tumor in 3 cases, or 1.5 per cent.; (19) dilated ureters from obstruction caused by tumor pressure in 2 cases, or 1 per cent.; (20) hydronephrosis (large size) from tumor pressure, in 2 cases, or 1 per cent.

2. The 1,188 cases collected by Noble, including cases operated in by A. Martin, Noble, Cullingworth, Frederick Scharlieb, and a series reported by Hunner and by McDonald, to which I add my own 200 cases, give a grand total of 1,388 analyzed cases, in which the complications were as follows:

	Per cent.
Carcinoma of the corpus uteri.....	32
Epithelioma of the cervix uteri.....	13

Pressure symptoms.....	15
Dilated ureters from tumor pressure.....	2
Hydronephrosis, large, from tumor pressure.....	2

3. In my observation with the non-operative treatment of fibroids of the uterus, based on more than 400 cases, I can speak with less definiteness because of my inability to tabulate results, and because of the difficulty in following many of the cases.

These cases naturally include those the symptoms of which were not so severe, probably 75 per cent. of all; those in which because of fear or prejudice the sufferers would not submit to radical procedures, approximately 20 per cent.; and finally, those cases which were so badly complicated or possessed such inherent conditions that radical procedures seemed unjustifiable, probably not more than 5 per cent.

I will speak first of those represented in the last 5 per cent. The percentage of non-operable cases in the future, will, of necessity, and for obvious reasons, be constantly diminished. Among them are cases complicated with vascular cardiac changes

of a grave degree; of grave kidney involvements; of widely disseminated septic conditions; of grave anemia with hæmoglobin below 25 per cent.; of complicating brain lesions; and, finally, grave complicating diseases of other organs, as pulmonary tuberculosis or visceral cancer.

However, we must be careful in relegating these cases to the list of incurable. In the last two years I have operated in two cases where the recoveries were gratifyingly prompt, although, from repeated and uncontrollable hæmorrhages the hæmoglobin had been reduced to 25 per cent. or less. I have successfully operated in a large number of cases in which serious chronic nephritis existed, such as seemed to preclude the justifiability of operation, in which the kidney symptoms were not only not increased, but decidedly abated. Several times I have operated and removed tumors and uteri where septicæmia and pyæmia existed to such a degree because of absorption and dissemination from the parts that operative interference seemed unjustifiable, in which cures were accomplished. Every surgeon who operates much grows to fear less these apparently hopeless cases, and should be in a position constantly to restrict the number to which he would refuse to lend aid with the knife.

In the 20 per cent. representing those patients who should be operated upon but refuse, we have an opportunity of watching the average case under general hygienic and the less radical forms of treatment, because the patients will accept no other. Such cases offer us an opportunity to watch the effects of ergot, general tonics, electricity, and the minor operative procedures, such as curettage and the ligation of the uterine arteries.

The 75 per cent. of cases in which the symptoms were not troublesome and in which the complications were not serious, include the small symmetrical growths which develop late in life, whose symptoms are a slight increase in the menstrual flow and some pressure symptoms, at those times especially, when the patient overexerts or at the beginning of menstruation, and which are symptomatically relieved by the menopause; those subperitoneal growths of single development which pedunculate and give rise to no symptoms and are frequently discovered only by accident; those of rather large size which rise above the pelvis and which do not increase the monthly flow, annoying only by their conspicuousness.

Many of these cases, especially if occurring in younger women, are liable to graduate from the symptomatically harmless class to the class giving rise to serious symptoms, and thus imperatively call for treatment. These apparently simple cases, too, should be looked upon with suspicion, because of unsuspected pathological complications, which, as

we have seen, are liable to exist either inherent to the tumor, or as an outside condition complicating it.

Those cases offer the field in which all kinds of conservative forms of treatment have from time to time each held momentarily the centre of the stage and the attention of the profession. Many of them give rise to few symptoms and if serious changes do occur, due warning is usually given of their approach. Unfortunately, however, even this rule has its exceptions.

A case of this description came under my observation in a young woman who was apparently in perfect health, but died suddenly of suppurative peritonitis. The post mortem showed a perforated intestine, which had become adherent and was then submitted to pressure of the tumor. A second case in a woman, 35 years of age, presented a rather large, apparently harmless tumor, without symptoms, in which an old adherent pyosalpinx was ruptured by a sudden forcible change of position of the tumor, and death resulted from diffuse peritonitis in twenty-four hours. Another, in perfect health, with a small tumor which had not been suspected, had an acute obstruction of the large intestine from impaction of the tumor and was saved only by a timely but serious emergency operation.

One more worthy of mention was that of a woman, 52 years of age, in whom the tumor had been pronounced harmless, as the menopause had apparently supervened, but who suddenly began to flow, and this continued for several weeks, until she was nearly exsanguinated. I saw the case in consultation, advised a dilatation of the uterus and curettement for diagnostic purposes, and discovered a smooth deep uterus with a senile endometritis which had apparently exposed a uterine venous sinus. A thorough curettement, cauterization, and the amputation of an enormously elongated cervix with ligation of the uterine arteries fortunately promptly relieved the patient.

There are many other cases less startling, which I could enumerate which at one time seemed to rest securely in this class.

METHODS OF TREATMENT.

I shall not dwell at all on the long list of drugs which have from time to time been employed in the routine treatment of fibroids of the uterus.

Galvanism.—I shall refer only briefly to the treatment by electricity, and by the ligation of the uterine arteries. I reserve a right to speak on these two subjects, because I was the first in America to make scientific use of electricity for the treatment of fibroids, and the first in any country to describe the treatment of vaginal ligation of the base of the broad ligaments, including the uterine arteries. Electricity (galvanism) will accomplish the following effects: (a) It acts as a powerful general tonic; (b) relieves hæmorrhage in symmetrically developed fibroids with no submucous projections; (c) promptly relieves neuralgic pains and frequently

pressure symptoms; (d) many fibroids will grow smaller under treatment, others will remain stationary in their development, while a few, usually the unsymmetrical, will not be affected.

These effects may be relied upon if the physician has the tact and perseverance to push the treatment, and the patient is willing to pursue a slow and at best an uncertain method of relief. I wish to say that with galvanism I have successfully tided many patients over the menopause who would have succumbed or become invalided without it, and have left them in perfect health symptomatically.

Vaginal Ligation of the Base of the Broad Ligament, Including the Uterine Arteries.—I have deliberately operated in forty cases of bleeding fibroids of the uterus by vaginal ligation of the uterine arteries through the base of the broad ligaments. I have operated in at least twenty in which one side has been ligated in connection with curettements or the vaginal enucleation of submucous fibroids.

The results of this simple and safe operative treatment have been almost uniformly gratifying in my experience. Its effect on exhaustive hæmorrhage has been uniformly prompt in relief of the flow. In at least three cases, however, it has not been permanent. In these exceptional cases the flow has gradually returned after a few months. In the meantime, however, in every case, the patient has had a substantial respite and, as the majority of these cases were those in which the hæmorrhage had been desperate and the patients reduced to the last extreme, the value of this respite can be appreciated. If this rational operative procedure had been described before hysterectomy became safe, it would have been one of the popular operative treatments, ranking with hysterotrachelorrhaphy as a conventional operation, and rivalling because of its greater safeness, the Battey-Tait castration as a treatment for fibroids. Now, however, while it will become finally established as one of several efficient means of dealing with fibroids and their many vagaries, it is destined to fill one of the small but, I trust, definite positions in the armamentarium of the surgeon instead of the ambitious place fondly hoped for it by its parent.

Myomectomies, the Battey-Tait Operation, and Hysterectomies.—My experience has led me to prefer abdominal hysterectomy with supravaginal amputation to myomectomy except when one or, at best, two centres of development, superficially located and so situated that they do not materially increase the area of the endometrium, are presented. Such tumors can be enucleated safely and when one can be positive that no other centres exist, a cure may be accomplished. I do not favor removing several centres, especially when one or more of them

are deeply seated; because, when there are several such centres of development, small ones which will later develop are sure to be overlooked and, besides, the operation is a more dangerous and mutilating one and one in which sepsis may be introduced from the uterine canal and in which hæmostasis may be defective.

The Battey-Tait operation of castration need only be mentioned in order to acknowledge our obligations to it in the days when we were learning, before we had discovered that hysterectomy was easier to do and more satisfactory in its results.

Hysterectomy, abdominal and vaginal, are the two operations which may be said to offer positive cures for fibroids of the uterus. Either will remove completely the tumor or tumors from the body and, at the same time, the tissue in which such tumors grow. Therefore, no matter how favorably we may look upon other forms of treatment, hysterectomy is the only sure remedy.

In the choice of a route for hysterectomy for fibroids of the uterus, I prefer the abdominal route, with supravaginal amputation of the cervix. The cervix is seldom the seat of fibroid development and when it is involved it is only by invasion from above. Hence the cervix should be spared unless it is the seat of a carcinoma, in order to preserve the proper contour and integrity of the vaginal vault. This is often of great importance in order to retain inviolate the most important function of the sexual organs. A vaginal hysterectomy or a panhysterectomy of necessity shortens the vaginal canal and leaves at its vault a painful cicatrix.

While hysterectomy is the only absolutely sure cure for fibroids of the uterus, we must remember that it has a legitimate mortality even in the hands of the most experienced surgeon. This mortality which will constantly grow smaller, I believe may be now stated as varying from a minimum of five per cent. in the hands of well trained surgeons constantly doing abdominal surgery, to 15 per cent. or higher in the hands of one only occasionally opening the abdomen. There is no operation in surgery in which the right kind of experience counts for more than in hysterectomies.

In the 200 consecutive cases recorded in this paper representing the last cases done by me, many of which were desperate, there were nine deaths, or a mortality of four and one half per cent.

In the future, this mortality will be greatly reduced because cases will be operated in early, before vascular and cardiac changes have taken place, before kidneys have been impaired by pressure, before tumors become large and unwieldy, before women have been reduced by exhaustive hæmorrhages, before tumors have become necrosed and infected,

before they have taken on the other degenerative changes so well illustrated by our statistics, and before they have become complicated with changes in the appendages.

In finally deciding upon a course to advise as a routine practice in the treatment of fibroids we must take all these things into consideration. No one can say that any particular patient is sure to recover from the immediate effects of operation, no matter how favorable it may appear. One of my nine cases of death in this series occurred from embolism in an apparently healthy woman, whose convalescence had been ideal and who was preparing to go home on the twenty-first day.

On the other hand, in the 1,388 analyzed cases presented in this paper, the operations revealed 32 cases of carcinoma of the body of the uterus, 24 cases of unsuspected sarcomas of the uterus, 70 cases of necrosed tumors, which were very liable to become infected and cause death, 53 cases of intraligamentous development of the tumor, which are so liable to produce kidney complications by ureteral pressure, and many other serious symptoms, 8 adenomyomas, 2 pregnancies menacing the life of the patient, 5 ectopic pregnancies; 8 dermoid cysts, 97 suspected or unsuspected true ovarian cysts, 12 parovarian cysts, 72 of pyosalpinx, 20 cases of appendicitis, 7 cases of intestinal obstruction, 2 cases of acute intestinal obstruction, 2 cases of obstructed ureters, 2 cases of hydronephrosis from pressure.

These serious conditions, incurable without operation, and unsuspected in the majority of instances, represented 31.6 per cent. of all cases operated in. This is the most instructive and startling thing about this analysis. Nearly one third of all the cases operated in were complicated with conditions very liable to prove fatal. And this does not take into consideration serious symptoms, the size of the tumors, and the various degenerations which are not necessarily fatal, and which are set forth in the same table.

When we take into consideration symptoms, too, as shown in my 200 cases, we have interesting food for contemplation. Dangerous hæmorrhage occurred in 41 cases, or 20.5 per cent.

CONCLUSIONS.

I. The routine treatment for fibroids of the uterus, presenting symptoms, in women under 45 years of age, should be supravaginal hysterectomy, except as hereinafter stated.

The exception to this rule should be (a) in subperitoneal tumors either pedunculated or not, in which only one or more distinct developments exist which do not materially increase the size of the uterus proper and the area of its endometrium, when myomectomies may be resorted to; (b) in

fibroids which present excessive hæmorrhagic tendencies, in which the hæmoglobin is reduced below 25 per cent., or in which serious vascular cardiac or kidney complications exist which greatly increase the risk of the operation, when a preliminary operation of vaginal ligation of the uterine arteries should be resorted to; (c) in cases where a radical operation will not be accepted, a curettement and vaginal ligation of the uterine arteries may be resorted to, or, if no operation at all will be accepted, general tonics, ergotine in tonic doses, and galvanism scientifically applied may be depended upon to relieve the patient materially, and occasionally tide them over the menopause to a complete symptomatic cure.

(2) The treatment for large, complicated tumors without regard to age, or large apparently uncomplicated tumors in which symptoms of hæmorrhage or pressure exist, should be supravaginal hysterectomy.

(3) Tumors of medium size apparently uncomplicated in women over 45 years of age may be managed by one of the less radical forms of treatment as: (a) when the tumors are of the symmetrical development type, enlarging uniformly the uterus, and the principal symptom is an exaggerated menstrual flow, the cases may almost invariably be relieved by galvanism and tidied over the menopause; or (b) if the growth is of the irregular type which has distorted more or less the uterine cavity, the case should be submitted to dilatation, finger exploration, curettement, and, if considerable flowing is a symptom, vaginal ligation of the uterine arteries, with the idea of obtaining a symptomatic cure over the menopause.

(4) The extremely small class of tumors coming under the head of "inoperable" cases must be managed on general principles—rest in bed, general tonics, treatment of the cardiovascular and kidney complications when they exist, curetting and irrigating for septic endometritis, electricity for pain and hæmorrhage, ligation of the uterine blood supply if practicable for intractable hæmorrhage, and vaginal incision of impacted cysts or pus accumulations.

103 STATE STREET.

Physicians' League of Buffalo.—At the annual meeting of the Physicians' League of Buffalo, held on May 31st, officers for the coming year were elected as follows: President, Dr. Jane W. Carroll; vice-president, Dr. Janet Himmelsbach; secretary and treasurer, Dr. Katherine Munhall.

The Fulton County, N. Y., Medical Society has elected officers as follows: President, Dr. McColloch, of Gloversville; vice-president, Dr. Mosher, of Johnstown; secretary, Dr. Lenz, of Gloversville; treasurer, Dr. Still, of Johnstown.

A SHOT AT CHRISTIAN SCIENCE FROM A TOY PISTOL.

By A. C. McCLANAHAN, M. D.,
CHICAGO.

There comes a time in childhood when, having outgrown the acoustic resources of your red rattle and your green whistle, you seek to give expression to your artistic moods through the medium of a toy pistol. This, beginning with the white color of new silver, fades in time to the leaden hue of ancient zinc. Although their noises may be the only attributes which endure these playthings to you, the colors are as real to you as are the noises; the noises are as real as the toys themselves. One day your playmate takes the pistol to a distance, and when he pulls the trigger you see a flash and a moment afterward hear a report. You wonder why the flash and the report did not occur together in this instance as they have always done before. Your playmate tells you that they did. He saw the one and heard the other at the same instant.

Why, then, did you not hear the report at the moment of its occurrence? You ask some older person, and he tells you that sound is something which must travel to the ear before it can be heard, and that to traverse a considerable distance it requires an appreciable time.

At this you wonder. If sound is something which can travel from the pistol to the ear, it cannot be a part of the toy as you thought it was. What is it like while it is on its way to the ear? You decide that it is precisely like what you hear. But what you hear is a sensation of sound. A sensation can exist only in a conscious mind. Does the air have a conscious mind? It seems hardly probable.

As you grow older you learn that the sound which you hear is merely the effect produced in consciousness by a cause that is wholly different from that effect. The cause is a motion of the air. The effect is the consciousness of sound. The cause is all that exists in the external world. The effect—the sensation of sound in consciousness—does not exist in any external object. It could not possibly exist outside of consciousness, and if all consciousness was to be destroyed, all sound, as the ear perceives it, would cease. The noise which seemed so real has been resolved into a mere effect produced on the mind by something wholly different.

"But the pistol still exists and is still white," you think, for childhood clings tenaciously to its illusions.

Poor boy, there are more real as well as more durable things than the whiteness of your toy pistol. Its whiteness is quite as illusory as its noise. It is an effect produced upon your eye by waves of an invisible, impalpable substance called ether. These

first strike the pistol, and are reflected by it to your eye, and there produce an effect which appears in your consciousness as color. The cause, which alone exists in the external world, is as different from the effect which it produces in your consciousness as the cause of sound is different from the sensation of sound. Undulating ether can no more be color, as you know color, than undulating air can be sound, as you know sound. If all consciousness was to be destroyed, undulations of air would still result from the percussion of material objects; waves of ether would still fall upon objects and be reflected by them to other objects; but sound and light, as you know sound and light, would vanish from the universe.

These illusions of color and sound were pleasant while they lasted. There was something satisfying in the belief that all the stirring sounds in the world, and all the gay colors, were real. It is hard to admit that they were mere pictures painted on the mind by an unknown artist in the outer world. It is hard to give them up, but you can let them go, you think, if they are unreal, and pin your faith to things that are less illusory. At least, the causes of these phenomena remain. The air and its waves, the ether and its undulations, and the pistol itself remain.

Let us see, my dear boy, to what you are pinning your faith. Ether, air, and the iron of your pistol are various forms of matter. If you observe a distinct portion of matter of any kind, you will perceive that its most conspicuous and apparently necessary property is its extension—its property of completely filling a certain portion of space. It is extended only so far as it is continuous. It occupies space only so far as it completely fills space. If there are interspaces between its parts, it does not extend through these interspaces and fill them, hence there is no matter there.

If you subject your piece of matter to sufficient pressure, you will reduce it to half its original volume. If you will now weigh it, you will perceive that nothing has been destroyed. The weight will not have been diminished in the slightest degree. Therefore, there were interspaces between the parts of the object, and you have simply reduced the volume of these interspaces by driving the parts of the object nearer to one another. Double the pressure and you double the diminution in the size of the object. Treble the pressure and you treble the diminution. This is the law of Mariotte, and if it has any limit, none has ever been discovered.

But if there is no limit to this law, what would be the effect of infinite pressure? The mind is staggered by the conclusion which it is forced to accept. Your poor toy would be crushed quite out

of existence, yet nothing would have been destroyed. Pressure cannot destroy matter. The unextended pistol would weigh as much as it ever weighed. Everything of which it ever consisted, except the interspaces, would still be present; the only effect of infinite pressure would have been to cause the disappearance of these interspaces. In reality the parts of your pistol are unextended points in space, more or less separated from one another, if we may accept the theory of Boscovitch, and I fear we must accept this part of it. Infinite pressure would merely cause the disappearance of matter as you knew matter. Everything that ever existed would still exist.

Then, in reality, the pistol never had any extension. In reality, it never completely filled the smallest portion of space. In reality, its most conspicuous and apparently necessary property is the effect produced upon your consciousness by a cause which is wholly different from that effect.

Is this effect caused by the undulation of something, as the noise of the paper cap is caused by the undulation of the air, and the metallic whiteness of the barrel by the undulation of the ether? "Must I resolve everything into undulations," you think. "What is it that silently undulates beyond the pale of consciousness in that strange, dark world of reality, where there is no color nor brightness—where the undulating thing itself has neither extension nor any other property which matter appears to have, and which yet causes, in the bright world of consciousness, the effects which I know as sound and color and extended matter? Is it an undulation that undulates?" This is unthinkable, but even if you could accept this unthinkable conclusion, you would have gained nothing, for as it has been shown that sound, light, and extension are mere effects produced on the mind by a cause that is different from any of them, so it could be shown that motion itself is another mental effect of an unknown cause. Your little toy pistol with its brave noise and metallic luster is gone. With it have gone the world of matter that you knew, the movements and colors of everything in it, the sounds and the odors, the tastes and the forms, and everything else perceived by the senses. A toy pistol in the hands of a boy has frequently done much damage. In your hands it has apparently destroyed a universe.

But do not imagine that you have reached the end of things. You stand, on the contrary, at the beginning. Your thinking, if it begins at all, begins here; and whether you think sense or nonsense depends upon the first step that you take from this point.

You have seen that nothing in the external world is what it appears to be—that the images in consciousness are wholly different from the reality in

the outer world that causes them. Only one step separates you from the insane idealism which asserts that there is no reality in the outer world—that there is nothing in the universe but mind, and that the phenomena of matter are nothing but the unreal phantasms of a mendacious mind. If you take this step you may become the worthy champion of any absurdity and the fit companion of any driveler. It would then be impossible to reach you by reason; but, if you were still accessible to reason, I would point out to you that you have no right to stop with the denial of the existence of an external world. You have precisely the same reason for denying the existence of mind that you have for denying the existence of matter; for as we have no other evidence of the existence of matter than the phenomena which it exhibits to consciousness, so we have no other evidence of the existence of mind than the phenomena which it exhibits to consciousness. If there is no reality behind the phenomena of the external world, there is none behind the phenomena of the world of mind. We know precisely as little of the one as we know of the other, and if we deny the existence of either, we must, in order to be consistent, deny the existence of both.

You have stood bravely by while one cherished illusion after another has been ruthlessly shattered and, kicking aside the wreckage of one dear belief, have gone resolutely forward to witness the equally ruthless destruction of the next; but at last you have reached a point beyond which the demolition of the universe cannot go, and from the ruin wrought by your toy pistol there emerges a reality so secure in its realness that it cannot possibly be destroyed, and can be escaped only at the price of the total abdication of common sense. This reality is the *cause* of phenomena.

That a thing exists is not valid evidence of its having been caused—it may have existed always. But if it exists as a phenomenon—as a change in consciousness—as something which begins to be—it is perfectly certain that it has been caused. You are conscious of the actual occurrence of mental impressions—changes in consciousness—which you do not cause; it is perfectly certain that they are caused by something; and since the cause is not within you, it is equally certain that it is in the external world.

An impression may, like that of a pencil moving over a piece of paper in the act of writing, or that of a flame impressing a piece of sealing wax, only remotely resemble the thing that makes it, for it is nothing but the necessary relation between that which causes the impression and that which receives it, and will necessarily vary with the nature of either, but its occurrence undeniably implies the

existence of both. The impression which the world makes on the mind of a frog is doubtless as different from that which you perceive as the structure of the frog's brain and organs of sense is different from the structure of your own. In neither case is the impression like the thing that makes it. In each the impression is a true picture of the relation between the mind impressed and the world impressing it.

There are phenomena, such as those of recollection and imagination, which you are conscious of causing yourself; but even back of these there is an external cause, for you are conscious that the material with which your recollection and imagination work—the very stuff of which your dreams are made—was furnished to the mind by an outside cause. It is of no consequence that you are as ignorant of the nature of the external cause as you are ignorant of the nature of the internal cause. There is absolutely no doubt as to the existence of either, even if both are merely two aspects of the same thing.

One mode of the external cause produces the phenomenon of a toy pistol. Another mode produces the phenomenon of a falling hammer. Another mode produces the phenomenon of a flash of light; and still another produces the phenomenon of sound. If the first mode is accompanied by the second, you know that they will be followed by the third and the fourth, and that each mode will cause its characteristic phenomenon in a perceiving mind. If there was no perceiving mind there would, of course, be no such phenomenon as a pistol, a moving hammer, a flash of light, or a sound; but the existence of the unknown reality and the coincidence and succession of its various modes would be as certain as ever.

While this incomprehensible reality is known only by the phenomena which its various modes present to consciousness, we know that it does not pursue an erratic course; that it does not act at random; that its modes eternally conform to the same immutable law that governs the phenomena themselves. To suppose otherwise would be to suppose that the same cause under different circumstances does not produce different effects, which, to a philosophical mind, is self evidently impossible.

From this it follows that if we adjust ourselves to the phenomena or appearances presented to consciousness by the external world, we shall have adjusted ourselves to the inscrutable reality which is the external world and which lies behind appearances as their cause. It follows, further, that if we ignore phenomena, if we suppress our consciousness of appearances, we shall not have annihilated the reality behind these appearances, and

shall be unable to adjust ourselves to its modes.

But this is the same as saying that we must regard the picture which the external world paints on our minds precisely as if that picture of a world was the world of reality itself, and that is exactly what I mean. It is a world of relative reality. Each part of the picture stands in unvarying relation to some mode of the absolute reality which alone exists. The phenomena of sound, color, matter, motion, and force are to us real sound, color, matter, motion, and force, and if in the practical affairs of life we regard them otherwise, we do so at our peril.

So you have your noisy little pistol back again, and with it come the solid world and all the things that made it like a world, the color and the movement, the energy and life, and back of all stands the inscrutable reality that was and is and ever shall be. Why, then, have I taken the trouble to destroy the world? If I meant to give it back why might I not have let you play on undisturbed, and spared myself the trouble, and you the terror of being left without a clod to stand upon?

For several reasons, and the chief was this: I feared that some one else might some day knock your world to pieces and might not know so well how to put it together afterward. It has often enough been knocked to pieces, and by some it has been put together afterward with wonderful skill; but to me it seemed needful to perform the trick on a scale so small that every man might feel that he could presently learn to reconstruct his own demolished world. For there is a cult of mystics who go about demolishing the world and teaching the credulous that this evil universe not only should not be put together again, but can by no possibility be put together; that it is nothing but the figment of unenlightened minds and cannot possibly be shown to have a basis of reality.

There is something apparently philosophical in the sophistry by which this conclusion is reached. It can certainly be shown that the world perceived by the senses is a world of mere appearances, and when you learn this, you naturally consider yourself superior to the untutored rustic to whom this world of appearances is absolutely real and independent of mind. You then come to feel that your superiority to the rustic would be greatly enhanced by denying that there is any reality behind these appearances; by asserting that the appearances of the poor world are actually the appearances of nothing; that there has been an appearance without anything whatever having appeared. In this moment of vanity you are persuaded to take the fatal step which would land you in complete intellectual nihilism if you continued to think, but, having taken it, you cease thinking. Your intellectual travels abruptly end. You listen to language so softly soporific that your

common sense falls gently to sleep, and what is left of your mind concludes that the highly sounding phrases to which it listens must mean something exceedingly fine, although you have not the slightest notion of what it is, and quite overlook the fact that they actually mean absolutely nothing at all. Some of the phrases in the text book of this cult, having no sense or meaning in whatever direction they may be read, have naturally the same meaning when read in either direction, and this is regarded an exceptionally excellent proof of their truth.

Having been reduced to the state of mental haze which enables your mind to float on the haze in the book, you are instructed not to apply physical measures to the relief of your illusory inconveniences and misfortunes. If there is anything you do not like, whether it be a protracted drought or a broken leg, you are told to call it a delusion, an error, a sin, or some other equally obnoxious and inappropriate name, endeavor to suppress your consciousness of it, and allow it to skulk back into that troublesome nothingness whence it originated and to which it belongs. If you burn your hand in hot lard there was no hot lard there, and therefore you did not burn your hand at all; the pain you feel is a sin, and therefore you do not feel it; if your hand nevertheless sloughs off, you never had a hand, and therefore you have not lost it; and as it was only an error, you are better off without it in any event.

Now, in order to save you from the deplorable consequences of believing this wholly senseless twaddle, I have knocked your little world to pieces myself for the purpose of showing you the sinister reality that lies unseen behind it, indifferent alike to abuse or prayers, inexorably consistent, resistlessly active, and wholly indestructible.

Believing you to be an intelligent youth, I have considered it unnecessary to dwell upon the obvious fact that the most insane conduct may incidentally be accompanied by some beneficial results. A doctrine which teaches men that every ill is purely imaginary and will surely be recovered from undoubtedly stimulates cheerfulness, courage, and hope; and these emotions, with as little doubt, exert an actually beneficial influence on the bodily tissues and sometimes enables them to throw off ailments to which they might otherwise succumb; but things have not yet come to so bad a pass that one must first become a raving maniac in order to have courage or look with hope into the future.

Again believing you to be a bright youth, I have not pointed out to you that the testimony of an idealist is altogether incompetent to establish the utility of idealism. You will not be likely to attach much weight to the testimony of a witness who proclaims the improvement which he has perceived

in his own person, after he has admitted to you that the whole content of his perception is a tissue of groundless illusions. If his senses are always wholly false, they have apprised him no more falsely of his illness than of his recovery. If their testimony is to be rejected in determining the existence of illness, it is to be rejected likewise in establishing the occurrence of a cure.

Since you have been clever enough to see these things without having them pointed out to you, it can hardly be needful to admonish you not to be too much impressed by the education and position of some of the exponents and advocates of therapeutical idealism. Of the few hundreds of thousands of these misguided ones who seriously subscribe to this faith, there are, it is true, many who occupy high places in the world and are apparently well educated with such education as a college can provide; but a college is not a brain factory, and high places have never been infallible preservatives or restoratives of sanity.

This form of madness is to be prevented, for it cannot be cured; and now in sorrow we may leave these dreaming world destroyers, together with the colleges which bred them and the high places which have advertised them, to the working out of their own salvation. It has been doubly profitable to notice them, for not only have we seen how we may escape the madness which has befallen them, but their creed has served with distinguished fitness to illustrate the fruits of that leaven of lunacy that is silently working in all classes of mankind throughout the world. Those of us who do not subscribe seriously to this particular form of foolishness usually subscribe seriously enough to some other form. It is hardly probable that there is another world whose inhabitants are more prone than those of this poor planet to band themselves together for the perpetuation of one or another variety of nonsense; for it is always hard to learn that the common sense that enables us to reconstruct a demolished world compels us to demolish many a pretty world of our own that we have constructed falsely.

160 EVANSTON AVENUE.

German Hospital, Buffalo.—On June 10th the incorporators met at this hospital and organized with these officers: President, Dr. William Simon; first vice-president, Dr. Edwin G. S. Miller; second vice-president, Dr. George Bleistein; third vice-president, Dr. William F. Wendt; fourth vice-president, Dr. Henry C. Zeller; secretary, Dr. Victor R. Blehdon; treasurer, Dr. Joseph Block; treasurer, Dr. Edward A. Weppner; director general, Dr. Jacob Stern.

THE PROBLEM OF THE TROPICS; THE INTERRELATION OF CERTAIN SOCIAL AND BUSINESS QUESTIONS.

By GEORGE ALLAN ENGLAND, M. A.,

MILTON PLANTATION, ME.

No less eminent a philosopher and sociologist than Benjamin Kidd has preached in his *Social Evolution* the absorption of the tropics of septentrional races, more specifically the so called Anglo-Saxon, and the exploitation of the indigenous population for their conquerors' benefit. The conquest, whether *vi et armis* or by the subtle but no less destructive methods of peaceful assimilation, is but the fulfilment of Seward's prophecy that the "Pacific Ocean, its shores, its islands, and the vast regions beyond will become the chief theatre of events in the world's great hereafter." Apparent even in the days when Kidd's epoch marking book appeared, it has of late assumed a large, one might almost say, a universal phase which has but substantiated the prophetic note of the past decade. To the British aggressions of that day and the rather tentative tropical outreachings of Italy, France, Germany, and Portugal must be at present added the scantily veiled desires of Russia toward Chinese and Indian control and the almost incalculable factor of American conquest and expansion in low latitudes.

Long before Kidd's day, even, this expansion of the great republic was prophetically shadowed forth by at least one clear sighted student of history and *Welttendenzen*, no other than the edifying Creasy, who, as far back as half a century, in his *Decisive Battles of the World* (1851), predicted the absorption of the Philippine Islands in no uncertain terms as follows:

"The importance of the power of the United States being then firmly planted along the Pacific applies not only to the New World but to the Old. Opposite to San Francisco lie the wealthy empires of China and Japan. Numerous groups of islands stud the larger part of the intervening sea, and form convenient stepping stones for the progress of commerce or ambition. The intercourse of traffic between these Asiatic monarchies and the young Anglo-American Republic must be rapid and extensive. The American will either buy or force his way, and, compared with the magnitude of such changes in the dominion of the Old World, the certain ascendancy of the Anglo-American over Central and Southern America seems a matter of secondary importance. Well may we repeat De Tocqueville's words that the growing power of this commonwealth is 'un fait entièrement nouveau dans le monde et dont l'imagination elle-même ne saurait saisir la portée.'"

Had Creasy lived until the present day he would have seen his prophecy fulfilled not only in the Pacific, but in the Atlantic as well, where the "bold,

intrusive, and unscrupulous" Americans, as he loved to call them, have already firmly established themselves. What the next half century may bring forth in the way of colonial expansion is still a problem for dreamers, politicians, and promoters to wrestle with; but we may feel confident that its greatest surprises will hardly be deemed as improbable as the present actuality would have been considered when the words just quoted were written.

The United States of America, so long the great conservative power, the stay at home and anti-expansionist republic, holds at the present day, through stress of circumstances both unforeseen and unavoidable, an aggregation of 175,000 square miles of picturesque and *opéra bouffe* islands in foreign parts. Nearly every foot of all this territory is in the tropics, where life is warm and primitively complex, where birth, growth, and death are all too rapid and where the indigenous loaf is scarcely as yet leavened by our soldiers and sailors, who form at present the only large class of resident Americans.

It is not difficult to perceive that racial, sociological, and climatic conditions all conspire against the establishment, in such a *milieu*, of anything like normal, average American life and that the American race, if it succeeds in establishing itself at all in the West Indies, in Hawaii, and in the Philippines, must more than ever manifest those qualities of adaptability which have thus far distinguished it. Physically, intellectually, and commercially the race must mould itself to meet the new conditions, its measure of success in this respect becoming also its measure of political and business supremacy.

In no other commercial undertakings are there such numerous and intimate relations with life under all its conditions as in the business of life insurance, which must seek out the physical, financial, and moral responsibility of its prospective clients and discriminate closely against unfavorable surroundings and habits and methods of life. Thus it happens in this new settlement of tropical countries, where considerable bodies of non-immune and unacclimated Americans have been and still are exposed to the unfamiliar and excessively trying conditions and necessities of life, that our recent military occupation has given rise to a number of problems, inquiries, and difficulties in the business of life insurance with which the preceding generation had nothing to do and for which there are to be found but unsatisfactory and partial solutions in the actuarial experience of the past.

"The colonial risk is at present distinctively a war risk," has been well remarked by E. B. Phelps, in his *Tropical Hazards*—a comprehensive book by an able writer. Soldiers and sailors, he points out,

are at present the only noteworthy class of Americans in the tropics, a class which he thinks will continue to be considerable and to constitute a variety of risks, distinct indeed, yet nearly enough allied to the conditions of civilian life to form a practical criterion therefor in the actuarial determination of premium charges. There are, even at the present moment, thousands of insurable persons in Cuba, Puerto Rico, and the Philippines, and the future will bring in other and indefinite thousands.

"The army," he says, "is blazing a road over which a much larger army of civilians will sooner or later press forward. When this migration actually sets in, various branches of American trade and commerce will materially develop on new lines, and conspicuous among the industries and vocations which will thus expand will be the insurance business with a hitherto undreamed of field for work before it."

No less surely is the army "blazing a road" for the actuaries in their calculations of risks incurred by travelers and residents in the same region. This branch of their science is so new that it is as yet hardly born—it is still in process of evolution and its development can still be watched. The past has little to teach regarding war and tropical risks. At the time of the Mexican war, in 1846, the entire amount of life insurance in the United States aggregated but \$6,000,000 and no war permits at all were issued by the two companies then in existence, the Presbyterian Ministers' Fund and the Mutual Life Insurance Company of New York. At the outbreak of the civil war an extra annual war premium of five per cent. was adopted, but even this was operative only north of the thirty-fourth parallel (about the northern boundary of Alabama), while for places farther south a still additional premium of like amount was charged. The population of the country in 1860 was but thirty-one millions, with 60,000 insured, a ratio of one to every 500. In 1898, at the beginning of the Spanish war, the population had risen to 75,000,000, one sixth of which number was insured for an average per capita amount of \$190.00, as contrasted with less than six dollars in 1860. During this conflict with Spain "the losses directly traceable to the war risks were comparatively slight, and none of the companies suffered, although the subsequent mortality due to impaired constitutions in consequence of service in Cuba, Puerto Rico, and the Philippines cannot yet be even approximately calculated." (Phelps.)

A new problem has, therefore, arisen with the crossing of the tropical Rubicon, where the climatic conditions (far worse than in even the least favored of the Southern States), have caused grave complications and induced many new diseases, despite

all the advance in antiseptic and surgical knowledge since 1860. "The impression that the tropical location of our new possessions constitutes a much greater hazard in the case of officers and men in the army than does the actual war risk now seems well nigh universal in life insurance circles." In these Southern lands it is the pestilence that walketh in darkness and the destruction that wasteth at noon-day which kills its thousands for every hundred slain by hostile lead.

How great the dangers are to men of Northern blood in tropical countries may be strikingly evidenced by the one fact that during 1898 and 1899, the two years of active warfare in the Spanish war, out of 747,080 admissions to sick reports, there died 6,080 men, only 1,150 from injuries, while 4,930 succumbed to disease. That is, the ratio of deaths by disease to the regular death that the layman always fancies attendant on the career of a "hero," was 4.28 to 1, an almost incredible proportion, were not the figures set down in black and white in government reports. Most unhealthy of all the tropical stations was Cuba, with a sick admission in 1898 of 3,413.54 per 1,000; least unhealthy were the United States camps, with an admission of 1,677.50 per 1,000. This figure, though far lower than that for any other station, was much higher than in the time of peace and speaks volumes against the care and sanitation of the camps. The greatest number of deaths from all causes took place in Cuba in 1898, being 91.55 per 1,000, or almost ten per cent., a frightful mortality, which fortunately sank, in 1899, to 18.30 per 1,000. Of the 91.55 deaths per 1,000 in 1898, 67.94 were from disease and only 23.61 from injuries, a low figure, comparatively speaking, which none the less attaches a most unpleasant stigma to the climatic and sanitary, or rather the unsanitary, conditions on the island. The mean monthly sick rate in 1899 was 211.41 per 1,000, a most extraordinary figure, often exceeded in the wet season despite the most vigorous work of sanitation. Fever, of course, caused most of the disability, of which Major Havard says in his *Report of July 10, 1900*: "It continues to strike when and where it listeth, regardless of the most reasonable expectations and best hygienic measures. Why the germ remains quiescent and inactive one or two seasons in the presence of susceptible material and then suddenly becomes active and violent is a question still unanswered."

In Puerto Rico, as elsewhere in the tropics, malarial infections, diarrhoeal diseases, yellow and typhoid fevers slew their thousands for every hundred men actually killed in battle, the rate in 1898 being 46.02 deaths per 1,000 from disease and only 2.46 from injuries. Smallpox, at first a serious menace, was promptly checked by a systematic

vaccination of the entire population, there having been effected 742,062 vaccinations and 116,955 revaccinations.

In the Philippines, deaths rose highest in 1899, when they reached 30.58 per 1,000, of which over half (15.30) were from disease. What the conditions were, in addition to those attendant on a destructive climate, may be inferred from the following brief remarks by Mr. Phelps:

"When the American troops first took possession of the Philippines the sanitary conditions of the various garrison towns and villages were execrable. Filth was everywhere and the hogs were the only scavengers. There has been a decided improvement in the conditions of the garrison towns, and under the direction of the board of health the city of Manila has known for the first time in its history the meaning of comparatively clean streets, a systematic removal of filth, and the serious attempt to enforce purity in its food supply. There can be no doubt that these sanitary measures will in time bring about a surprising change in the hygienic conditions of the cities and towns of the Philippine Islands, and their systematic execution, the gradual education of the natives to a realization of their self interest in compliance with the health regulations, and the segregation of the lepers, the sufferers from bubonic plague, and the smallpox patients, are certain materially to reduce the death rate in the Archipelago."

The greatest mortality was caused by forced marches, changes of location, and the fatigues, exposures, and excitements of campaigning in an unfavorable climate. The mean monthly admission to the sick rate in 1899 was 183.86 per 1,000, with a death rate at times as high as 9.36 per 1,000, mostly due to malarial and diarrheal diseases and fevers. Diseases of the respiratory organs were and are less prevalent than in the United States. The board of health did excellent and effective work, otherwise the death rate would probably have been far greater. Vaccination was vigorously carried on to such an extent that from October, 1899, to July, 1900, there were but seven deaths from smallpox in Manila as compared with 75 in March alone of 1899. While resting the troops fared vastly better, of course, than when in the field. As General Sternberg remarks in his latest *Report*, the opinion is prevalent among our medical officers that in time of peace and doing only garrison duty, the sick rate of the army in the Philippines would be no higher than it ordinarily is in the Southern States, yet even under the most favorable conditions, one can hardly doubt the deleterious effect of tropical life. Its dangers are recognized by British observers as well as by our own, India having proved a constant drain on the vital resources of its Northern conquerors. As Spencer Thompson, of the Standard Life Assurance Company of London,

says in his *Notes on Mortality in India and Some Other Tropical Countries* (recently presented at the fourth actuarial congress in New York City):

"Doubtless a sound and healthy constitution free from taint of disease will in many cases tell favorably; but a number of diseases which prevail in India, and which on the most sanguine computation it will take many years to stamp out—such as cholera, malarial, and other fevers—may attack the strongest, while fatal accidents are also probably more common than in the United Kingdom."

Again, Col. Charles R. Greenleaf in his *Report* of July 13, 1900, remarks:

"Nearly all the diseases of the tropics produce an effect on the general economy that does not follow similar diseases in the temperate regions—that is, a lowering of the vital force to such a degree that full recovery of health becomes impossible so long as the patient is in the tropical climate, and doubtful after his return to a residence in a temperate climate. Apparently the only disease from which complete recovery may be expected by residents at any one of the sanitary points of the island is malaria, but after such recovery reinfection frequently follows exposure. Tuberculosis is rapidly fatal, rheumatism becomes chronic, and I think that even the hot springs of the country, which have a great repute among natives for their cures, will not be effective with Americans. Homesickness is a potent factor in producing the conditions of melancholia into which many of the diseases have passed. The isolation of the troops, their lack of knowledge of the native language, their enforced confinement to the towns they garrison, and the constant strain incidental to continued preparation against attack by the army combine to produce the mental condition which, for want of a better name, is called 'insanity.' That this condition is a serious one is evidenced by the fact that the majority of suicides occur in this class of cases."

And still further says G. A. Harmon in his *Report on the U. S. S. Baltimore*:

"There is an unmistakable falling off in the physical stamina, a perceptible narrowing of the margin of reserve vitality. This is exhibited in the graver character of ordinary trifling injuries and ailments. Slight abrasions are hard to heal, and, without the most careful attention, degenerate into sluggish ulcers. Mild bronchial catarrhs are persistent and show a tendency to produce loss of tone, weak heart action, and general debility; skin eruptions become chronic, and, finally, within the last month or two a number of cases of the local *febris tropica*, the calentura of the Philippines, have made their appearance. The health of the ship is naturally better than that of the army or the marines stationed on shore, thanks to the less degree of exposure to paludal and climatic causes of disease, but there is no doubt that the long stay in these waters is beginning to exercise a deleterious effect upon the crew."

The navy, however, in the long run, fared vastly better in almost every respect than the army, prov-

ing conclusively that conditions incident to life ashore, rather than the heat and oppression of the tropics, were responsible for the high sick rate and large number of deaths. Both naval officers and men were exposed to materially less danger from disease and injury than those on land; they had better food, purer water, and more sanitary surroundings. There was in fact but a very slight increase in serious sickness over years of peace, the rate being, for example, 853.53 per 1,000 in 1895, as against 871.69 in 1898.

Out of 23,986 men serving in the navy in 1898, only 173 deaths took place, a ratio of 7.21; in 1899, out of 20,819 men, there were 153 deaths, a ratio of 7.35. A surprisingly small number of these were due to injuries. For example, in 1898, 118 were due to disease and only 55 to injuries. The highest number of deaths took place in the Asiatic station in 1899, where 26 men died, a very slight number for a force of 4,652. More men, in fact, died in navy yards, barracks, etc., in the United States, as, for example, when in 1899, out of 3,684 men so stationed, 27 deaths took place. "The advantages of the naval force afloat over the men ashore is emphasized by the fact that in neither 1898 nor 1899 did the admission rate of the men in the Asiatic squadron reach that of the naval force ashore." The usual malarial and febrile diseases played a small part in the sick list, being offset, unfortunately, by venereal diseases, which afflict a very large proportion of sailors when they reach port after a long cruise.

The picture of tropical service is, on the whole, not a pleasant one, nor apt to inspire confidence in an insurance company. In view of facts such as these it can hardly occasion wonder that American life insurance has from the beginning been very reluctant to accept men either residing or traveling in the tropics. To quote Mr. Phelps again in his *Tropical Hazards*:

"The first policies issued by the Mutual Life Insurance Company of New York and the Nautilus Insurance Company, in the early '40's, practically prohibited the insured to travel south of the thirty-sixth parallel (about the latitude of Nashville, Tenn.). The companies which came after them, prior to the civil war, set up the same defenses against the tropical hazard, and for years the Southern boundary line of Virginia and Kentucky was practically the Ultima Thule of American life insurance."

At the present day a census of sixty-four leading American companies has given results as follows: Regarding travel or residence in the tropics, two companies place no restriction whatsoever on their policy holders; four impose a permanent restriction; one restricts policy holders between July 1st

and November 1st, and three impose restriction for a term of years (usually two) after taking out the policy. War service is unrestricted by only eleven companies, seven forbid it for a term of years (usually two, as in the former case), and forty-six prohibit it permanently.

That such discrimination should be made is entirely reasonable and easy of comprehension, the more so as even the appalling mortality of war in low latitudes is not the only factor to be reckoned on by actuaries. Figures for death and immediate illness do not, of course, show the effects of lingering diseases and constitutional deterioration. The best that can be done by the actuary is to make the most practical deductions possible from the figures as shown, assuming that civilian experience will, in the long run, coincide with or at least approach that of a continued military occupation; and, acting upon these data, to construct an entirely new set of tables and guides for the determination of premium rates. The greatest diversity at present exists among American companies in this matter, a diversity too extensive to permit of treatment here. One thing may, however, be confidently expected, that the recent tropical expansion of the United States will furnish materials and criteria for the continued evolution of actuarial science.

Therapeutic Notes.

NOTES ON THE NEWER MATERIA MEDICA

(Continued from page 1173.)

Acidol is the shorter name adopted for betaine hydrochloride, which forms colorless water-soluble crystals containing 23.8 per cent. of absolute hydrochloric acid. On account of the fact that it undergoes hydrolysis in contact with water to yield a solution of hydrochloric acid, acidol is recommended as a substitute for that acid. Five decigrammes of acidol is the equivalent of five drops of pure hydrochloric acid or ten drops of the diluted acid. As acidol exerts a caustic action in the undiluted form, it is preferably administered dissolved in water or mixed with some harmless vegetable powder or with pepsin. Tablets containing 0.5 gramme of the pure substance are also put up by the manufacturers.

Alban's Cera-Salve is composed of wax, 10 grammes; olive oil, 16 grammes, and lead acetate, 4 grammes.

Aluminum Carbonate, which up to now had been considered impossible of production, is produced in the form of a chalky-white, easily powdered substance. It is tasteless, readily absorbed, and possesses mild styptic and astringent properties which adapt it for use in the treatment of diarrhœa.

NEW YORK, SATURDAY, JUNE 17, 1905.

THE ACTINOMYCES BOVIS.

We have received the first number of the *Publications of the Massachusetts General Hospital*, which, it is announced, are to be issued from time to time as suitable material is available, such as selected papers and reports based upon clinical and pathological investigations conducted in the hospital and in its laboratories. The first issue consists of an essay entitled *The Biology of the Microorganism of Actinomycosis*, for which the Samuel D. Gross prize of the Philadelphia Academy of Surgery was awarded. The author is Dr. James Homer Wright, director of the Clinicopathological Laboratory of the Massachusetts General Hospital and instructor in pathology in the Harvard Medical School. The essay presents 56 pages of text and 57 very handsome reproductions of photomicrographs. It is manifestly the result of a very thorough study of the subject.

Dr. Wright does not accept the prevailing belief that the specific infectious agent of actinomycosis is widely disseminated in the outer world in the form of one of certain branching microorganisms which differ profoundly from *Actinomyces bovis* in having sporelike reproductive elements. These organisms, he thinks, should be grouped into a separate genus, *Nocardia*, and the infection produced by them should be termed nocardiosis.

marked by absence of the granules characteristic of actinomycosis.

He believes that the usual habitat of *Actinomyces bovis* is the secretions of the buccal cavity and gastrointestinal tract of man and certain animals, though he cannot at present prove that this is the case. "In these secretions," he says, "it should not exist in the characteristic forms seen in the lesions, but it probably will be found in the form of fragmental filaments growing in company with bacteria and not now differentiated from them." As to the foreign bodies often found in actinomycotic lesions, he does not think that they carry the microorganism into the tissues, but by their traumatic and irritative effect furnish a nidus for it on its accession from its normal habitat, and thus enable it to develop into characteristic colonies and produce the lesions of actinomycosis.

THE "SPOTTED FEVER" OF THE ROCKY MOUNTAINS.

A disease popularly termed "spotted fever" has been known in Idaho for about thirty years, and in Montana, especially in the Bitter Root Valley, ever since the first settlement of the region by white men. Other popular names for it are "tick fever," "black fever," "blue disease," and "black measles," and some of the learned have applied to it the name of piroplasmosis hominis on the theory that it is due to infection with a protozoon of the genus *Piroplasma*. Charles Wardell Stiles, Ph. D., chief of the Division of Zoology of the Hygienic Laboratory of the United States Public Health and Marine Hospital Service, has recently made a very thorough study of the disease, and the Treasury Department has published his account of the investigation. Dr. Stiles has failed to confirm the *Piroplasma* theory, and he has not identified the microorganism upon which the disease probably depends, but he has contributed an account of its clinical history and pathology that must go far toward establishing in the future positive knowledge as to its nature and ætiology.

According to Dr. Stiles, Maxey, in 1899 (after other observers had given briefer definitions), described the affection as "an acute, endemic,

non-contagious, but probably infectious febrile disease characterized clinically by a continuous, moderately high fever, severe arthritic and muscular pains, and a profuse petechial or purpurial eruption in the skin, appearing first on the ankles, wrists, and forehead, but rapidly spreading to all parts of the body." The exanthem is said to be lacking in some mild cases, and in others the nervous perturbation is of a character to suggest cerebrospinal meningitis, though no signs of that disease are found post mortem and Kernig's sign is not observed. The aetiology is manifestly an inviting field for further research, and Dr. Stiles's investigation will doubtless stimulate its further study.

THE DANGERS OF ELECTRICITY.

A useful pamphlet prepared by Mr. D. Kleber has recently been published in Berlin. It deals with the dangers of electricity, both in the form of lightning and in that of the strong artificial currents employed in electric transportation and the other electric devices that have come into extensive use of late years. The author directs his efforts largely toward minimizing danger by improvements in the conduction of the current, so that his work appeals more to engineers than to the medical profession. Nevertheless, the pamphlet conveys much information that is of interest to physicians, compiled largely from the writings of Eulenburg and Jellinek.

The author reminds us of the well known fact that the skin is much more resistant to the current than the organism as a whole, adding that there are certain parts of the body, such as the throat and the rectum, that are particularly vulnerable. Again, the condition or peculiarity of an individual in regard to resistance to the electric current is of an importance hardly secondary to that of the strength of the current, so that it is not very uncommon to read of men having survived the passage of a current generally accounted deadly, whereas in other instances a current of very low voltage has produced death.

There is a singular variation among animals as to their susceptibility to electricity, and the horse falls a victim to currents much less in intensity than those necessary to kill many other

animals. In the cases of both man and the lower animals it is difficult to establish a minimum lethal voltage, so diverse are the effects of the current in different instances; therefore it behooves boards of health and all persons concerned in electrical construction and installation to allow amply for any possible high degree of susceptibility.

SUBWAY VENTILATION.

In the issue of this *Journal* of November 12, 1904, shortly after the opening of the subway, I wrote an editorial entitled *The Problem of Ventilation of Our New Subway*. In it I referred to the already perceptible and very characteristic odor of badly housed humanity, and, although not a prophet, I ventured to wonder what this odor, perceptible after two weeks of use in cold weather, would be after some months of heavy travel in summer? The complaints about the well nigh unbearable atmosphere in the subway, which are making themselves manifest in recent editorials in our leading newspapers and in letters of protest against existing conditions by the public, are evidence that things have turned out as I feared. Not even the analysis of the subway atmosphere by a great and celebrated chemist, who attempted to prove that the air in the subway was as good as the air in our streets, if not better, or the wide distribution of a pamphlet which indicated that the subway was equal to a health resort, can efface the effect on the travelers which a half hour in a subway car now invariably produces.

In the editorial I viewed the subway situation from a bacteriological standpoint, pointing out that numerous pathogenic microorganisms thrived there when there were moisture and darkness; they lose their virulence or become entirely innocuous when exposed to sunlight and air for a sufficient length of time. The grippe bacillus, the coccus of pneumonia, and the tubercle bacillus are perhaps the three which are most to be feared when confined to darkness and moisture. According to Koch, for example, the tubercle bacillus can be killed by exposure to the direct rays of the sun in from a few minutes to two hours, according to the thickness of the mass of tuberculous matter exposed. Straus experimented

with thin layers of dried sputum, and after an exposure of half an hour the bacilli had lost their virulence and no cultures could be produced from them. If expectorating in street cars, exposed to light and air, but ill ventilated, must be considered a source of propagation of infectious diseases of the respiratory organs, how much more must this hold good of subway cars only artificially lighted and with still less fresh and pure air!

Some tests made by a distinguished bacteriologist, afterward made public, showed that scrapings taken from the iron railings and several samples of dust taken from other sources of the subway were relatively free from pathogenic microorganisms. Whether these tests justify the lessening of precautions urged by the Health Department to combat respiratory infectious diseases I will leave to the judgment of higher authorities. As for myself, I am willing to say that there do not exist sufficient well kept spittoons, and that the signs prohibiting expectorating are not taken care of or conspicuous enough even where they are allowed to remain.

Some medical man recently said that it was difficult to prove that a single case of tuberculosis had been developed from indiscriminately expectorating on the sidewalk and the floors of conveyances, public buildings, etc. Let me hope that the sanitary advisers of the Rapid Transit Company do not consider this as evidence against the utility of precautions. We cannot trace the bacillus from its ejection from the consumptive into the system of the non-consumptive, where it takes months to develop, but we know that the enforcement of sanitary regulations concerning the indiscriminate deposit of sputum has resulted in a marked reduction of the morbidity and mortality of tuberculosis. Before the inauguration of the educational campaign by Dr. Hermann M. Biggs, of the Department of Health, and the enactment of a law against indiscriminate expectoration in street cars and public places, the mortality among the inhabitants of New York was forty per cent. greater than it is now.

To begin by rendering the subway sanitary, at least from a bacteriological point of view, let the Interborough Company work hand in hand with

the Department of Health in enforcing rules against indiscriminate expectoration, and thus minimize the danger of spreading infectious respiratory diseases. We have recently been spared any serious epidemic of acute respiratory diseases, such as grippe, but I am free to say that I feel greatly apprehensive of the consequences should we be visited by such an epidemic before conditions in the subway have been improved. To trace an infection of grippe, an acute disease of rapid development, to its source, might be easier than to trace one of tuberculosis, which is of slow evolution, and to make the spitting regulations more effective in the subway, I would reverse the usual method of putting numerous signs, reading "Do Not Spit," and put a sufficient number of well kept spittoons in convenient places with the sign "Spit Here Only." I venture to say that this would be more effective than the negative command.

To be just to the Interborough Rapid Transit Company, let us say that, according to the publications, they are willing to follow any suggestion, coming from sanitary engineers or experienced contractors and builders, as to the best way of improving the condition of the subway air. Numerous more or less complicated schemes have been suggested to the authorities, but these seem to have been found ineffectual. Perhaps the reason for this is that there is no single method sufficient to render the atmosphere in the subway relatively pure and sanitary. Only by a combination of all can we look for any appreciable result. I will enumerate those which, in my humble opinion, should be resorted to, and I hope that the Interborough Company will take my criticism and suggestions in a spirit of kindness.

We all know the inestimable value of the subway to the metropolis, and the more sanitary subways we have, instead of nerve racking elevated roads, the better it will be for our community. Throughout the extent of the subway there should be as many air and light holes as possible. Run with the motive power at hand, pumps or blowers could be placed at appropriate intervals over the subway to draw out the bad air and to force in good air. These pumping stations, of

course, should not be placed in narrow streets, but preferably in squares, small parks, or wide streets. Not to make them unsightly, shrubs or trees should be planted about them. All signs attached to railings in stations should be removed at once to insure a freer circulation of the air. Along both walls of the subway road there should be placed powerful revolving fans, so that the air current produced by those on one wall should be in the opposite direction to that produced by the others. Good sized electric fans for special ventilation of the stations should be added to the system of fans along the tunnel in order to help purify the atmosphere. The roadbed of the entire subway line should be kept moist by a sprinkling apparatus which could easily be attached to a number of trains, and thus allay the dust. Whether oil or water is best suited for this purpose will have to be found out by experimenting with both liquids. The dust, which invariably must result from the dirt brought into the cars by the thousands of passengers on the soles of their shoes, should be combated by a daily, if not twice daily, cleaning of the floors by the now well tried pneumatic exhausting process. Smoking in stations should be prohibited, and the broom for the purpose of dry sweeping should be banished. Mops alone should be used to clean the platform and stairs; the floors should be mopped regularly after the rush hours. While not exactly appertaining to the subject of ventilation, it would give additional comfort to the traveling public if the cars were remodelled and all new ones constructed like those in use on the Brooklyn Bridge or in the Boston Subway, with doors opening in the middle as well as at the ends of the car. The middle door would of course serve for passengers to leave the car, and the end door for those entering. Walker's system for the better ventilation of the cars should be given a thorough trial. In this system holes open from the "sash deck" toward the roof. A shingle extends outside the car, between the holes. As the car moves, the shingle's interference throws the fresh air into the first opening, while circulation forces the impure air out at the second. In addition, I would suggest numerous small fans, distributed throughout the cars, which should be put in motion on

especially hot days. I venture to say that it will well pay the Interborough Rapid Transit Company even to have a corps of men, especially trained, to look after the proper ventilation and sanitation of the subway.

I am convinced that by a combination of all these suggestions the Rapid Transit Company will render travel in the subway much more hygienic and much more pleasant. The health of its own employees will be better, the service more efficient, and accidents rarer. In an ever growing metropolis, like New York, the subway must become our most important means of travel between our homes and places of business. We shall have to have more subways and longer ones. Therefore it is the duty of the Interborough Rapid Transit Company to render this means of transportation as sanitary as possible, in its own interest as well as that of the millions of New York's citizens who are and will be obliged to use it all the year around.

S. A. KNOPF.

THE SUBWAY TEMPERATURE.

Concerning the air of the New York subway in its serious relations to the health of those who travel in it or are employed on the trains, Dr. Knopf treats in his usual vigorous way in this issue of the *Journal*. As to its temperature—a matter that may prove to be more than one of comfort or discomfort—it must be conceded that it has lately been high. Recalling, however, the fact that during the cold weather of last winter the subway was comfortably warm, we may assume perhaps that during a period of summer heat of several days' duration—which has not yet happened this year—the temperature, like that of a cellar, will be lower in the subway than above ground. This consideration should, of course, not be held as absolving us from every effort to renew and purify the air in the conduit.

THE FINAL FATE OF PARAFFIN INJECTIONS.

Some doubt as to the permanency of the cosmetic and other desirable results of paraffin injections may have arisen as the result of investigations by Eschweiler, who is reported to have found an injected mass in process of disintegration at the end of a year. But later observations by Broeckaert, reported at a recent meeting of the French Society of Rhinology, Otolology, and Laryngology (*Presse médicale*, May 27th), tend to show that encystment occurs, rendering absorption unlikely.

News Items.

Society Meetings for the Coming Week:

MONDAY, June 10th.—New York Academy of Medicine (Section in Ophthalmology); New York County Medical Association; Hartford, Conn., Medical Society; Chicago Medical Society.

TUESDAY, June 20th.—New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y.; Baltimore Academy of Medicine.

WEDNESDAY, June 21st.—New York Academy of Medicine (Section in Genitourinary Surgery); New York Society of Dermatology and Genitourinary Surgery (private); Woman's Medical Association (New York Academy of Medicine); Medicolegal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark); Philadelphia County Medical Society.

THURSDAY, June 22nd.—New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Celtic Medical Society; New York Orthopaedic Society; Brooklyn Society for Neurology; Pathological Society of Philadelphia; Church Hill Medical Society of Richmond, Va.

FRIDAY, June 23rd.—New York Society of German Physicians; Philadelphia Clinical Society; Philadelphia Laryngological Society.

SATURDAY, June 24th.—New York Medical and Surgical Society (private); Harvard Medical Society, New York (private).

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending June 10, 1905:

	June 10—		June 3—	
	Cases.	Deaths.	Cases.	Deaths.
Measles	770	18	727	17
Diphtheria and croup	322	30	320	27
Scarlet fever	152	13	152	14
Smallpox	1	1	1	1
Chickenpox	120	1	113	1
Tuberculosis	339	167	393	142
Typhoid fever	49	10	78	4
Cerebrospinal meningitis	52	57	21	60
	1,805	295	1,815	264

Endowment for Nassau Hospital.—Thomas W. Albertson, treasurer of the Nassau Hospital Association, and cashier of the Nassau County Bank, has received from Mrs. James R. Willets, a check for \$3,000, the amount to be used for endowment of a bed at the Nassau Hospital, to be known as the James R. Willets bed, in memory of her late husband.

Tuberculosis Among Negroes.—A special class for the treatment of pulmonary tuberculosis among negroes has been started at the Department of Health's Clinic for the Treatment of Communicable Pulmonary Diseases. This class will be held on the evenings of Tuesday, Thursday, and Saturday of each week, from 8 to 9 p. m., and only negroes will be seen on those days and hours. The establishment of such a class was due to a request made by the Afro-American physicians of New York; they believing that the colored people would attend such a special class more readily. The physicians in attendance are negroes, and arrangements have been made for the services of a colored nurse. The physicians are:

Dr. P. A. Johnson, 203 West Thirty-third Street, laryngologist; Dr. W. H. Johnson, 103 West Twenty-ninth Street; Dr. A. A. Kellogg, 151 West Fifty-third Street; Dr. A. S. Reed, 314 West Fifty-second Street; Dr. J. F. Thorpe, 418 West Thirty-sixth Street; Dr. E. P. Roberts, 242 West Fifty-third Street, attending physicians.

These physicians were recommended by the Medico-chirurgical Society (colored) of New York at a special meeting held on June 4th. Treatment and medicines are, of course, free; and the patients will be visited at their homes by the tuberculosis nurses of the department. Negroes may attend any of the other classes of the clinic, which is open daily from 9 to 4, and on Monday, Wednesday, and Friday evenings from 8 to 9.

PHILADELPHIA.

Marriages.—Dr. E. Forest Bickel, of Shamokin, Pa., and Miss Florence Simons were married on June 7th.

Dr. Mervyn Ross Taylor and Miss Jeannette Reilly were married on June 7th.

Dr. Howard R. Faringer, of Mount Holly, N. J., and Miss Gertrude E. Leopold were married on June 8th.

Scientific Society Meetings for the Week Ending June 24th.—Tuesday, June 20th, Dermatological Society. Wednesday, June 21st, Philadelphia County Medical Society (business meeting for members only); Association of Clinical Assistants, Wills Hospital. Thursday, June 22nd, Pathological Society; Entomological Section, Academy of Natural Sciences. Friday, June 23rd, Northern Medical Association.

The Annual Meeting of the Botanical Society of Pennsylvania was held in Biological Hall, University of Pennsylvania, on June 3rd. Among the collections exhibited was one from Arizona by Mrs. W. F. Ladds, one of drugs used by the Indians by Dr. L. Rosa Minoka, and one from Santa Barbara, Cal., by Miss Martha B. Shoemaker. Dr. Adolph W. Miller presided at the meetings.

The Health of the City.—The following cases of transmissible diseases were reported to the Bureau of Health for the week ending June 3, 1905:

	Cases.	Deaths.
Typhoid fever	130	13
Scarlet fever	53	1
Chickenpox	55	0
Diphtheria	92	9
Cerebrospinal meningitis	3	1
Measles	65	2
Whooping cough	10	2
Tuberculosis of the lungs	26	69
Pneumonia	27	24
Erysipelas	4	1
Tetanus	1	1

The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 10; dysentery, 1; diarrhea and enteritis under two years, 21. The total deaths were 450, in an estimated population of 1,438,318, corresponding to an annual death rate of 16.20 per 1,000 population. The total infant mortality was 98; under one year, 80; between one and two years, 18. There were 39 still births, 24 males and 15 females. The temperatures were not excessively high; the maximum recorded by the weather bureau was 82° on

the 20th. There were thunderstorms on May 28th, May 30th, and June 2nd. The total precipitation was 0.71 inch.

Charitable Bequests.—By the will of Miss Caroline Stevenson, who died on June 4th, the Presbyterian Home for Widows and Single Women in the State of Pennsylvania receives \$1,000 and the Presbyterian Orphanage \$5,000.

The thirty-eighth anniversary of the Methodist Episcopal Home for the Aged, at Belmont and Edgeley Avenues, was held on June 8th. Three thousand dollars were received in donations and as the proceeds of a sale held on the grounds.

Miss Eliza Wood has donated \$10,000 to the Home of the Merciful Saviour for Crippled Children for the endowment of two beds.

Personal.—Dr. B. W. Fassett, of Courtney, N. C.; Dr. E. L. Erhard, of Glassport, Pa., and Dr. Arthur A. Pratte, of Hinsdale, N. H., are registered at the Philadelphia Polyclinic.

Dr. R. Tait McKenzie demonstrated Jiu-jitsu methods before the eighth annual conference of Young Men's Christian Association Physical Directors of Pennsylvania on June 10th.

Dr. Edward Martin, Director of the Department of Public Health and Charities, was painfully but not seriously injured in a trolley accident on June 7th. Dr. Martin was still confined to his room on the 11th instant, but was improving steadily.

Resolutions Adopted by the Alumni of Jefferson Medical College:

Whereas, The Alumni Association of the Medical Department of the University of Pennsylvania have recently honored Professor William S. Forbes, an alumnus of the Jefferson Medical College, by the presentation to him of a loving cup, with resolutions of esteem, in recognition of his successful efforts in securing the passage of the Anatomy Act of 1883, in the State of Pennsylvania, and

Whereas, The agreeable relations already existing between these two schools of medicine are thus augmented and individual friendships are more firmly cemented by such action; therefore, be it

Resolved, That the Alumni Association of the Jefferson Medical College does hereby express to the Alumni Association of the Medical Department of the University of Pennsylvania, its earnest appreciation of the honor bestowed by this visible and lasting evidence of their professional regard for one of our most worthy and beloved alumni, and

Resolved, That the Alumni Association of the Jefferson Medical College recognizes the sincerity and felicity of the presentations so gracefully voiced by Professor George A. Piersol; and, further, be it

Resolved, That a copy of these resolutions be sent to Professor George A. Piersol, representing the Alumni Association of the Medical Department of the University of Pennsylvania, to Professor William S. Forbes, to the trustees of the Jefferson Medical College, and to the leading medical journals. By order of the Executive Committee of the Alumni Association of the Jefferson Medical College; Charles S. Barnes, recording secretary.

Opening of Summer Outing Grounds for Poor Children.—The Country Nursery at Chellen Hills opened for the summer on June 5th. In this charitable institution the children of the poor, sometimes with their caretakers, are allowed to spend a week in the country. Many children go to the nursery for the day, the institution being reached by the trolley lines to Chestnut Hill.

Last year 10,000 children and their caretakers visited the nursery.

The Children's Sanitarium at Red Bank, N. J., was opened for the summer on June 10th. The sanitarium, which is administered by the Sanitarium Association of Philadelphia, provides a day's outing on the banks of the Delaware River for the children of the poor of Philadelphia. The society owns two steamers, which make five trips each way daily. Last year 97,000 people were entertained at Red Bank; 12,521 adults, 7,779 infants under two years of age, 23,216 children between two and five years of age, 47,759 children between five and ten years of age, and 5,785 children over ten years of age. The property consists of bathing pools, games, amusements, hospital, diet kitchen, dining rooms, and a physician and nurses are in attendance. The expenses of the association are met by private subscription and an appropriation from the State. The following are the officers of the association:

President, George D. McCreary; vice-president, Monroe Smith; secretary, Dr. Eugene Wiley; treasurer, William S. J. Wetherill; solicitors, Attorney General Hampton L. Carson, Norman Grey, and Alexander L. Rogers. The board of managers includes also Dr. William B. Atkinson, Charles Thackara, James D. Winsor, John F. Coombs, Samuel Y. Heebner, W. Atlee Burpee, John Roberts, Edwin S. Dixon, and William E. Speakman.

GENERAL.

The Medical Missionary Society, of Nova Scotia, elected the following officers on May 30th: President, Dr. Stewart; vice-presidents, Dr. MacDonald and Mrs. H. Harrington; treasurer, Dr. Cowie; corresponding secretary, Mrs. Dickey; recording secretary, Dr. Weaver.

The City and Female Hospitals, of St. Louis.—The following thirty-two physicians were successful in the recent examination held in St. Louis to determine eligibility to internship in the two institutions mentioned: City Hospital:

Dr. Walter Fischel, Dr. M. D. Schoemaker, Dr. Conrad B. Vonnahme, of East St. Louis; Dr. C. B. Caldwell, of Monticello, Ill.; Dr. Eugene J. Brihach, Dr. B. C. Kern, Dr. P. D. McMillan, of Maryville, Mo.; Dr. Louis K. Guggenheim, Dr. Jesse W. Hale, Dr. R. D. Alexander, of Oak Ridge, La.; Dr. George M. Park, Dr. V. B. Kieffer, Dr. H. F. Lincoln, Dr. Jerome E. Cook, Dr. Leo C. Huelsmann, Dr. William J. Carter, of Gays, Ill.; Dr. Bert M. Brewster, of Macedonia, Mo.; Dr. Edmund F. Tackey, Dr. A. M. Gregg, Dr. John A. Wilkens, Dr. A. J. Chalkley, Dr. Sherwood Moore, Dr. George Hawkins, of Paris, Mo.; Dr. Robert C. Strode.

The doctors receiving Female Hospital assignments are:

Dr. C. M. Barr, Dr. Z. D. Lumley, of Kampsville, Ill.; Dr. Edwin L. Sheahan, Dr. Roy E. Mason, Dr. Max W. Jacobs, Dr. Clarence E. Betts, of Lovington, Ill.; Dr. Elmer E. Curtis, Dr. Oscar S. Coppedge.

The Johns Hopkins Hospital School for Nurses graduated the following on May 24th:

Corra Baker, of Stillman Valley, Ill.; Sarah Barnes, of Baltimore; Emma Batterman, of Brooklyn, N. Y.; Bessie Beck, of West Hartlepool, Eng.; Katrine Blackinton, of Blackinton, Mass.; Julia Bradfield, of La. Grange, Ga.; Mary Bunting, of La Crosse, Wis.; Mary Carter, of Baltimore; Ina Chambers, of Woodstock, Can.; Mollie Cook, of Baltimore; Alice Dammann, of Baltimore; Lillian d'Espard, of Toronto, Can.; Martha Ellison, of Richmond, Va.; Helen Erskine, of Newville, Pa.; Catharine Finney, of Harris-

burg, Pa.; Elizabeth Geddes, of Toronto, Can.; Isabel Grant, of Charlottesville, Va.; Ida Green, of Toronto, Can.; Elsie Hardenbergh, of Minneapolis, Minn.; Frances Hewes, of Catonsville, Md.; Clara Illig, of Ilion, N. Y.; Dorcas Jamieson, of Toronto, Can.; Gertrude Jones, of Wilkesbarre, Pa.; Lucy Kent, of Wytheville, Va.; Sarah Knox, of New York; Kate Lownsbrough, of Toronto, Can.; Cora McCabe, of Baltimore; Frances McQuaide, of Harrisonburg, Va.; Helen Mullen, of Hamilton, Can.; Ruby Riley, of Brooks, Ky.; Estella Rooth, of Toronto, Can.; Mary Rosser, of Rustburg, Va.; Lila Simpson, of Frederick, Md.; Edith Smith, of Huntington, N. Y.; Carrie Sparrow, of Montreal, Can.; Katherine Steelman, of Philadelphia, Pa.; Marion Vannier, of Sierra Madre, Cal.; Helen Wadland, of Woodstock, Can.; Helen Wilmer, of Baltimore.

North Carolina State Board of Health.—The annual meeting of the State Board of Health was held recently in Greensboro during the session of the State Medical Society. Four of the nine members retired this year. The State Medical Society filled two of the vacancies by the reelection of Dr. George G. Thomas, of Wilmington, N. C., whose term was expiring, and Dr. Thomas E. Anderson, of Statesville, N. C. The Governor appointed two members also, naming Dr. J. Howell Way, of Waynesville, N. C., and Dr. W. O. Spencer, of Winston, N. C. All the appointees are regarded as men of unusual ability. Dr. Thomas is the chief surgeon of the Atlantic Coast Line Railroad, and has been identified with the work of the board for a number of years. Dr. Way has been very active in the affairs of the profession, and has done good work on the State Board of Medical Examiners and as secretary of the State Medical Society for some years past has done much to make the revision plan of the American Medical Association a success in North Carolina. His appointment by the Governor gave great satisfaction to the profession. Dr. Thomas is well known to the profession, having been a member and secretary of the State Examining Board for several years. Dr. Spencer is the family physician of the Governor, and stands well in the profession in his section of the State.

Personal.—Dr. P. W. Ward has resigned the position of president of the Cleveland, O., Board of Health, and has been succeeded by Dr. J. D. McAfee.

The Maryland General Hospital staff for the ensuing year consists of: Resident physician, Dr. L. B. Cravens; assistants, Dr. Robert L. Blake, Dr. Ernest H. Gaither, Dr. B. W. Carey, Dr. Clarence B. Collins; in charge of lying-in hospital, Dr. George Rosenbaum; resident pathologist, Dr. L. E. Langley.

To take up the practice temporarily of her father and uncle in Rochester, Mich., Dr. Millie E. Wilson, for two years house physician at Emergency Hospital, Detroit, and the first woman physician to hold that position, has resigned from the hospital staff, and Dr. Margaret R. Otis has taken up her work.

Dr. Ira Applebee, of 318 South Pearl Street, has been appointed surgeon to the bureau of fire, Albany, N. Y., vice Dr. Louis Le Brun, resigned, to go to Europe. Dr. Applebee took up his new duties on June 7th.

Dr. J. J. Hoffmann, who graduated from the Ohio Medical College about two years ago, and

who for the past year has been identified with the German Deaconess Hospital, of Cincinnati, has been tendered an important position as a member of the medical staff of the Indiana State Insane Asylum.

The members of the Susquehanna County Medical Association, of Binghamton, N. Y., gave a banquet to Dr. W. L. Richardson at the Tarbell House on June 7th, in honor of his ninetieth birthday. A large number of physicians were present.

American Pædiatric Society.—This society will hold its seventeenth annual meeting at the Sagamore, Lake George, N. Y., June 19, 20, and 21, 1905. Programme:

The Use of Sodium Citrate in Infant Feeding, by Dr. Henry L. K. Shaw, of Albany; High Per Cent. Fat in a Mother's Milk, Producing Severe Enterocolitis in Her Infant, by Dr. W. P. Northrup, of New York; Acid Auto-intoxication in Infancy and Childhood, by Dr. John Lovett Morse, of Boston; Case of Sepsis in the Newly Born, by Dr. A. Jacobi, of New York; A Case of Acute Yellow Atrophy of the Liver in a Child, by Dr. A. H. Wentworth, of Boston; Presentation of a Heart Case, by Dr. Henry L. K. Shaw, of Albany; Report of a Case of Stenosis of the Pylorus in Infancy, by Dr. J. P. Crozer Griffith, of Philadelphia; Two Operative Cases of Pyloric Stenosis in Infants, by Dr. Thomas Morgan Rotch and Dr. Maynard Ladd, of Boston; A Case of Congenital Extrophy, with Extroversion of the Bladder, and Other Anomalies, by Dr. A. C. Cotton, of Chicago; A Plea for the More Timely Use of Intubation in Laryngeal Stenosis, and for the Use of Tracheotomy in Certain Neglected Cases, by Dr. E. W. Saunders, of St. Louis; On a Subject to be Announced, by Dr. F. Huber, of New York; Congenital Defect of the Brain, by Dr. George N. Acker, of Washington; The President's Address, by Dr. Charles G. Jennings, of Detroit; A Case of Acute Lymphatic Leucæmia in a Child Aged 14 Years, by Dr. A. D. Blackader and Dr. A. D. Gillis, of Montreal; A Study of the Leucocyte Count in Bronchopneumonia, Lobar Pneumonia, and Empyema of Infants and Children, by Dr. Henry Heiman, presented by Dr. Henry Koplik, of New York; Leucocytosis in Influenza, by Dr. F. S. Churchill, of Chicago; A Case of Uncinariasis in a Child, by Dr. Samuel S. Adams, of Washington; An Unusual Case of Tuberculosis in an Infant, by Dr. Charles W. Townsend, of Boston; Temperature, Pulse, and Respiration Relationships in Infancy and Childhood, by Dr. Myer Solis-Cohen, presented by Dr. J. P. Crozer Griffith, of Philadelphia; Milky Non-Fatty Effusion in a Case of Hodgkins's Disease, by Dr. D. L. Edsall, of Philadelphia; The Results in Children of the Decapsulation of the Kidneys for Nephritis, with the Report of an Apparently Successful Case in a Child Aged Twenty-six Months, by Dr. Edwin E. Graham, of Philadelphia; An Analysis of 141 Cases of Typhoid Fever in Children, by Dr. Alfred Hand, Jr., and Dr. J. C. Gittings, of Philadelphia; Note on the Frequency of Empyema in Children Under Two Years of Age, with Remarks on the Diagnosis of Empyema in Infancy, by Dr. D. J. Milton Miller, of Philadelphia; The Eye Symptoms of Infantile Scurvy. Autopsy—Large, Infected Retrobulbar Hæmatoma, by Dr. Irving M. Snow, of Buffalo.

Examination for Panama Canal.—Hospital Interne (Male). The United States Civil Service Commission announces an examination on July 12 and 13, 1905, to secure eligibles from which to make certification to fill vacancies in the position of hospital interne under the Isthmian Canal Commission on the Isthmus of Panama. Two days will be required for this examination. As an insufficient number of eligibles resulted from the examination held on January 18th, for this position, qualified persons are urged to enter

this examination, to which men only will be admitted. Each applicant for the Isthmian Canal Service will be required to submit to the examiner, on the day he is examined, a photograph of himself, taken within three years, which will be filed with his examination papers as a means of identification in case he receives appointment. An unmounted photograph is preferred. The date, place, and kind of examination, the examination number, the competitor's name, and the year in which the photograph was taken should be indicated on the photograph. Full information concerning transportation to the Isthmus, conditions of employment, etc., is contained in Form 1417. Age limit, 20 to 30 years on the date of the examination; salary, \$50 a month, with board and quarters, provided that if appointees are retained in the position of interne after one year they will be paid \$125 a month. Only graduates of reputable medical schools having a three years' course will be admitted to this examination. The examination will consist of the subjects mentioned below, with the relative weights indicated:

<i>Subjects.</i>	<i>Weights.</i>
1. Letter writing (the subject matter on a topic relative to the practice of medicine).....	5
2. Anatomy and physiology (general questions on anatomy and physiology, and histological or minute anatomy).....	15
3. Chemistry, materia medica, and therapeutics (elementary questions in inorganic and organic chemistry; the physiological action and therapeutic uses and doses of drugs).....	10
4. Surgery and surgical pathology (general surgery, surgical diagnosis; the pathology of surgical diseases).....	20
5. General pathology and practice (the symptomatology, aetiology, diagnosis, pathology, and treatment of disease).....	25
6. Bacteriology and hygiene (bacteriological methods, especially those relating to diagnosis; the application of hygienic methods and prophylaxis and treatment).....	10
7. Obstetrics and gynecology (the general practice of obstetrics; diseases of women, their pathology, diagnosis, symptoms, and treatment, medical and surgical).....	15
Total.....	100

This examination is open to all citizens of the United States and also to aliens who comply with the requirements, provided that aliens appointed for service on the Isthmus of Panama shall not be eligible for appointment or transfer to any other branch of the public service. The county officer's certificate in the application form need not be executed. No person will be appointed for service on the Isthmus who is not physically sound and in good health. Persons appointed to positions under the Isthmian Canal Commission will be expected to proceed promptly to the Isthmus. Persons examined for positions under that commission will not be eligible, as the result of such examination, to positions in the United States or Philippine services. Applicants should at once apply to the United States Civil Service Commission, Washington, D. C., for application form 1312. The medical certificate in form 1312 must be filled in by a reputable practising physician. No application will be accepted

unless properly executed and filed with the commission at Washington. In applying for this examination the exact title as given at the head of this announcement should be used in the application. As examination papers are shipped direct from the commission to the places of examination, it is necessary that applications be received in ample time to arrange for the examination desired at the place indicated by the applicant. The commission will, therefore, arrange to examine any applicant whose application is received in time to permit the shipment of the necessary papers.

Statement of Mortality in Chicago for the Week Ending June 10, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	June 10, 1905.	June 3, 1905.	June 11, 1904.
Total deaths, all causes.....	314	467	420
Annual death rate per 1,000.....	15.46	23.22	21.36
By sexes:			
Males.....	307	245	247
Females.....	207	221	173
By ages:			
Under 1 year.....	96	73	66
Between 1 and 5 years.....	44	71	32
Over 60 years.....	108	87	73
Important causes of death:			
Acute intestinal diseases.....	18	23	24
Apoplexy.....	19	11	15
Bright's disease.....	46	37	25
Bronchitis.....	7	14	16
Consumption.....	70	47	63
Cancer.....	19	17	21
Convulsions.....	9	6	5
Diphtheria.....	4	8	6
Heart diseases.....	48	59	33
Mosles.....	12	9	1
Nervous diseases.....	12	24	12
Pneumonia.....	73	49	52
Scarlet fever.....	1	1	3
Smallpox.....	1	0	0

Stroke.....	1	0	0
Typhoid fever.....	8	7	1
Violence (other than suicide).....	38	31	36
Whooping cough.....	8	15	3
All other causes.....	120	95	97

A sunstroke in April and overcoats, wool blankets, and another sunstroke in June are the sufficient explanation of the increase of mortality in of the two most healthful months in the year. The 47 more deaths than in the previous week and the 94 more than in the corresponding week of 1904 represent increases of 10.4 and 18.4 per cent., respectively, in the annual death rates per 1,000 of the population. The erratic weather is chiefly responsible for the 23 more deaths from consumption and the 24 more from pneumonia than reported during the week of June 3d. These two of the most important causes of death exhibit some remarkable features, comparing the two pneumonia seasons of this year and last. Consumption shows an increase of 48.8 per cent. in its mortality rate, while pneumonia shows a decrease of 14.3 per cent. Following are the figures for the two seasons:

PNEUMONIA, CONSUMPTION AND ALL CAUSES.—TWO PERIODS OF 224 DAYS COMPARED.

	Deaths from—	All causes.	Consump- tion.	Pneu- monia.
October 30, 1904, to June 10, 1905.....	18,868	2,044	2,950	
November 1, 1903, to June 11, 1904.....	18,433	1,950	3,354	
Per cent of total deaths—				
October 30, 1904, to June 10, 1905.....	12.12	17.48		
November 1, 1903, to June 11, 1904.....	10.58	18.19		
Death rate per 10,000 of population per annum—				
October 30, 1904, to June 10, 1905.....	16.85	24.25		
November 1, 1903, to June 11, 1904.....	11.35	28.32		

Pith of Current Literature

LYON MEDICAL

May 14, 1905.

1. Thrombophlebitis of the Longitudinal Sinus in a General Paralytic, By M. LANNOIS and A. JAMBON.
2. A Case of Subphrenic Empyema Diagnosed Exclusively by Means of the Radioscope. Basculation of the Two Parts of the Diaphragm, By E. DEVIC and A. CHALIER.

1. **Thrombophlebitis of the Superior Longitudinal Sinus.**—Lannois and Jambon report a case of general paralysis which was following a rapid course when an unexpected complication took place. A little while after a lumbar puncture the patient had a sudden epileptiform attack, followed by hemiplegia of the right side. He soon after died and autopsy revealed the presence of a thrombosis of the superior longitudinal sinus.

2. **Subphrenic Empyema.**—Devic and Chaliere report a case in which a diagnosis of subphrenic empyema was made with the radioscope, although no physical signs of the presence of such a condition could be made out. The diagnosis was confirmed by exploratory puncture and the abscess was opened on the following day. Another interesting observation made with the radioscope was that the two portions of the diaphragm moved in opposite directions like see-saw, a true movement of basculation. The patient died eight days after the operation was performed.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

June 10, 1905.

1. Differential Diagnosis Between Coxa Vara and Other Static, Inflammatory, and Traumatic Affections of the Hip Joint, By NICHOLAS SENN.
2. Chorioepithelioma Malignum. With Report of a Case, By P. BROOKE BLAND.
3. Proprietary Therapeutics, By HORATION C. WOOD, JR.
4. Federal Control of Vaccine Virus, By JOHN F. ANDERSON.
5. The Advantages of Expeditious Surgical Work, By ROBERT T. MORRIS.
6. Treatment of Psoriasis by the General Practitioner, By DREUW.
7. What is Dyspepsia? By FENTON B. TURCK.
8. Puerperal Arthritis, By EDWARD C. MORSE.
9. The Sequence of the Pathological Changes in Appendicitis; a Study of the Significance of the Lesions Found in Different Stages of Appendicitis, Based on the Pathological Findings in a Series of Operative Cases, By E. MACD. STANTON.
10. Immunity. Chapter XVI (Concluded).

1. **Coxa Vara.**—Senn writes an elaborate paper on the symptomatology, diagnosis, and treatment of coxa vara. Outside of Germany, the condition is little understood, hence the importance of calling attention to it. A genuine coxa vara is characterized by a non-inflammatory softening of the neck of the femur, accompanied or followed by a downward bending and torsion. The condition has been thought to be an expres-

sion of late rachitis. It occurs usually between the ages of fourteen and eighteen, though the author reports a case which occurred in a man of forty-two years. The condition is most often mistaken for coxitis.

2. **Chorioepithelioma.**—Bland reports one case of chorioepithelioma. With this for a text he writes a very complete formal paper on the subject.

5. **Expeditious Surgical Work.**—Morris reports briefly twelve operations (consecutive) during which he was timed. No special effort was made to break any records. The author holds that after a patient has been on the table over fifteen minutes his resistance against infection is greatly reduced. It is well therefore to try to finish most operations within fifteen minutes.

6. **Psoriasis.**—Dreuw recommends the following ointment for psoriasis:

R Acid. salicylic. 3iiss;
Chrysarobin, Ol. rusci (birch tar), aa. 3v;
Sapo. virid., vaseline, aa. 3viiss.

For from four to six days the ointment is applied by the aid of a stiff brush to the affected area (after this has dried somewhat it is well to apply a little starch or zinc powder). On the fifth or sixth day the patient starts taking hot baths daily for from one to three days, and after the bath vaseline is to be well rubbed in from one to three times a day. This course of treatment, which embraces a period of eight days, may be repeated several times, according to the severity of the disease, but as a rule the psoriasis patches disappear soon after the first treatment.

8. **Puerperal Arthritis.**—Morse contends that every arthritis occurring during the puerperium is septic in character, and that there is really no such thing as an arthritis of a distinctly rheumatic character.

 - (d) Notes on Operations for Renal and Ureteral Stone, By PAUL THORNDIKE.
 - (e) The Diagnosis of Renal and Ureteral Calculi, By BENJAMIN TENNEY.
 - (f) The Aids to Diagnosis of Renal Calculi Obtained Through the Examination of the Urine, By H. F. HEWES.

1. **Surgery of Calculi.**—Cabot reviews in a very brief way the chief points of interest concerning ureteral calculi. He reports nine personal cases and points out the practical lessons,

from the operative point of view, that may be drawn from each case. (b) Cunningham analyses forty-eight cases of renal calculus, nineteen of which were operated upon, and one case of ureteral calculus which have been treated at the Boston City Hospital. (c) Cabot, in his study of the cases of calculus treated at the Massachusetts General Hospital, excludes, for one reason or another, all but twenty-six cases. On these patients, thirty-three operations were performed, and six died. As to the permanency of results: Of the 20 patients who survived operation, 13 have either been seen, or have been communicated with, recently. Of these 13, 10 have been entirely relieved and are well to date. With the remaining three the situation is as follows: One had large double calculi, and two operations were done, separated by an interval of a few months. He has been entirely relieved of pain, from which he suffered for years, but still continues to have a purulent urine and occasional attacks of irritability of the bladder. One still has pain, referred to the bladder and prostate, for which no cause has been found. There has been no recurrence of pain or bleeding from the kidney. One continues to have pain in the kidney and pass gravel at irregular intervals, as before operation. (d) Thorndike discusses only certain points in the technics of operation upon the kidney or ureter. His observations are based on his personal experience, and are somewhat disconnected and fragmentary. (e) Tenney systematically covers the diagnosis of renal and ureteral calculi. His paper is in two parts. In the first he discusses the usual data upon which a diagnosis is based, that is, the symptomatology and the condition of the blood and of the urine. In the second part he discusses the special means of diagnosis; the x ray, catheterism of the ureters, and cystoscopy. (f) Hewes asserts that the actual feasibility of the diagnosis of calculus by urinary examination may be stated as follows: The presence of gravel or a movable stone in the kidney or pelvis or ureter is in all probability recognizable by a urinary examination in the vast majority of cases, provided that the urine is obtained at the time of the acute process or attack. A fixed stone in the kidney or renal pelvis, on the other hand, shows as a rule no definitely diagnostic signs in the urine. Occasionally, as in the instance of the excretion by the ureter of an ammoniacal urine, it may do so. In the majority of cases of this affection we have simply the signs of a pyelitis of varying grades. Where conditions are quiescent a slight sediment of leucocytes alone occurs. Where inflammation is active large quantities of pus and some blood and casts are seen. If decomposition of urea occurs in the pelvis we have the phosphatic deposits with the ammoniacal urine. The existence of these pyelitis signs, together with other symptoms, such as pain or the history of previous intermittent spells of hæmaturia, is always suggestive, but nothing more than suggestive. In certain cases of stone the passages may become occluded, under which condition no evidence of disorder may be found in the urine.

MEDICAL NEWS.

June 10, 1905.

1. Mosquitoes of Florida, By HIRAM BYRD.
2. Suicide; Its Consideration from a Medical Standpoint, By RALPH WAIT PARSONS.
3. Immigration—The Medical Examination of Immigrants and What the Nation is Doing to Debar Aliens Afflicted with Trachoma, By GEORGE W. STÖNER.
4. "Sore Throat": As Caused by Systemic Conditions, By NATHAN G. WARD.
5. Medicinal Treatment of Affections of the Thyroid Gland, By CHARLES M. GRANDY.
6. A Very Simple Method to Locate the Stomach, By MARK I. KNAPP.
7. Drainage After Laparotomy, By L. A. EWALD.

1. **Mosquitoes.**—Byrd asserts that Florida can boast of raising about twenty-two species of mosquitoes. The whole of North America, according to Giles, harbors 36 species, and recently it has been alleged that New Jersey alone contains the same number. The world at large can probably boast of 500 species, though to date only about 300 have been described and accepted. From the sanitary point of view the *Anopheles* and *Stegomyia* are the most important. The former are the malarial carriers (Florida has five species of this genus), and the second are the yellow fever carriers (Florida has one species, the *Fasciata*, which, however, is accused of being the real and only culprit of the genus). In addition to these two very important diseases, it is known that mosquitoes transmit the filaria, probably the trypanosoma, and the specific cause of dengue. They are also held responsible for certain animal diseases. The author discusses in a general way the habits of mosquitoes and their mode of propagation, and gives advice as to the best way of ridding towns and communities of these dangerous pests.

2. **Suicide.**—Parsons asserts that suicides have doubled in frequency during the past ten years. He believes that if the subject once attracts the attention it deserves, suicides among the mentally afflicted can be materially diminished. In order to gain a clear understanding of the subject, it is well to consider it under three heads: (1) Suicide which occurs as the result of an imperative conception; (2) suicide of the sane; (3) suicide of the insane. Very much condensed, the author's advice amounts to this: The insane, with suicidal tendencies, should be watched by competent attendants and not by members of the family or other unskilled persons. Means of self-destruction should be kept out of their way.

3. **Immigration.**—Stoner describes the methods by which the government inspects immigrants. Last year about eight thousand aliens were excluded on medical grounds. Of these, nearly one tenth were excluded at the port of New York, on account of trachoma.

5. **Affections of the Thyroid Gland.**—Grandy summarizes his advice thus: We may have goitres with excessive secretion or goitres with too little secretion, which can as a rule be distinguished by the pulse rate. When the symptoms are not too urgent try thyroid extract and iodine in the

latter and rest treatment and blood from thyroidectomized animals in the former class, but, if these measures are of little avail and the symptoms demand it, do not hesitate to call on a competent surgeon to partially remove the gland.

6. **To Locate the Stomach.**—Knapp recommends the following, not very accurate, method of locating the stomach: The patient sits or stands, with the clothing freed, but the abdomen not uncovered. He is made to drink a glass of ice water. In about half a minute the cold from the stomach will spread to the overlying skin and can be recognized by the examiner's hand.

7. **Drainage.**—Ewald holds that it is an impossibility to effectually drain the peritoneal cavity. Drainage has its chief use in cases in which the intestines have been injured and repaired, but in which there is some doubt as to whether the stitches will hold. Instead of relying on drainage, it is best so to treat a patient that the chances of a general infection will be reduced to a minimum. This is best accomplished: (1) By careful indication for operation and operative procedure. All those patients who show a severe infection through high temperature and other symptoms should be operated upon only when operation is made necessary to save life, and then a preliminary vaginal incision should be made. We know that pus located intraperitoneally or in the parametrium is highly infectious. (2) By selection of the proper time for operative procedure. Pus from a pyosalpinx is sterile after nine months. When no immediate indication for operative interference exists, it is better to wait. (3) By careful observance of the following preventive measures: Protection of the abdominal cavity with layers of gauze; careful separation of adhesions; removal of all visible pus; exact hæmostasis, and rapid operative procedure.

MEDICAL RECORD.

June 10, 1905.

1. A Contribution to Hæmophilia, with Special Reference to the Joint Symptoms of the Disease,

By FRANCIS P. KINNICUTT.

2. Remarks on the Ætiology of Fissure in Ano,

By J. RAWSON PENNINGTON.

3. On the Early Diagnosis of Pulmonary Tuberculosis,

By G. R. POGUE.

4. Encephalomenigeocele, By WILLIAM D. HAGGARD.

5. Is Craniotomy on the Living Child Ever Justifiable?

By I. MARX.

6. Gunshot Wounds of the Abdomen,

By JOHN EGERTON CANNADAY.

7. Cushion Diseases,

By JEROME D. POTTS.

1. **Hæmophilia.**—Kinnicutt reports one case of hæmophilia which he had under observation for seven years. At the end of this time the patient died. The case possessed many points of interest: Its congenital yet not ascertainable inherited character; the frequency and severity of the arthritic attacks; the involvement of the smaller joints (the hand) on one occasion; the eventual development of permanent structural changes of the joints; and, finally, the occurrence of intraabdominal hæmorrhage and death, probably from this cause. The author summarizes the present views regarding the treatment of

hæmophilia as follows: (1) The internal administration of the lime salts, especially of the chloride of calcium, in doses of two grammes (30 grains) twice or thrice daily. Its continued use should be interrupted every two or three days by a period of twenty-four hours. The salt is soluble in 1.5 parts of water and is well borne by the stomach. (2) The application of solutions of the same salt, with compression, for accessible surface bleedings. Aqueous solutions of one half per cent. are efficient. Another convenient mode of employment is in the form of a finely powdered chalk mixed with one half per cent. solution of the calcium chloride. The less soluble lime salts, such as calcium phosphate, are equally efficient for local application. (3) The use of a combination of a one half per cent. solution of calcium chloride and one sixth volume of a solution of nuclealbumin, for local application. The nuclealbumin can be obtained from aqueous extracts of various cellular tissues—testicle, thymus, thyroid, ovary, etc. If the prepared extracts are not available, a supply may be procured readily by mincing any of these tissues in a weak alkaline solution ($\frac{1}{500}$ solution carbonate of sodium) and filtering through gauze after a few minutes. (4) The application of a stream of carbonic acid gas to the bleeding surface, in accessible hæmorrhage. Its inhalation, freely mixed with ordinary air or oxygen, in concealed hæmorrhage. (5) The use of four per cent. solution of cocaine hydrate for surface bleedings, and also of adrenalin ($\frac{1}{1000}$) with compression.

2. **Fissure in Ano.**—Pennington holds that the chief predisposing factor in the occurrence of fissure in ano is anatomical. He devotes his paper to demonstrating that the posterior quadrant of the anal margin is the weakest of the four. But why a fissure should occur at all is not explained. The author's conclusions are: "(1) The dorsal surface is the most frequent location of fissure in ano, the anterior the next and the sides the least. (2) The dorsal surface receives the least support from the muscular cylinder that surrounds the anal canal, the anterior the next, while the sides receive the greatest. (3) Experimentally, with and without anaesthesia, a conical end dilator, when forced into the anal canal, tears the dorsal surface first and almost universally, the anterior occasionally, and the sides rarely. (4) From the foregoing it will be seen that the sequential points of muscular weakness, experimental tears, and location of fissure in ano correspond."

3. **Pulmonary Tuberculosis.**—Pogue holds that one should not wait to be too sure before making a positive diagnosis of pulmonary tuberculosis. If one waits until the diagnosis can be proved it will be too late to save the patient. It is better to err on the right side than on the wrong, and, as Dr. Hall has said, "It is better that ten men should be cured and our diagnosis be in doubt in some of the cases, than that five should be dead and five permanently disabled and we be 'dead sure' that all had suffered from tuberculosis." For reaching an early diagnosis the tuberculin test is of great value. The author

has never seen bad results follow its use in properly selected cases.

4. Encephalomeningocele.—Haggard reports one case. The patient was operated upon and died. At birth a tumor of the size of a goose's egg was present on the back of the child's head. It grew progressively, and at the age of four months measured 23 inches in its long or transverse diameter, and 17 inches in the horizontal diameter. The tumor was kidney-shaped, and together with the child had to be carried on a pillow with great care. The child weighed 6 pounds and the tumor 5 pounds after removal. It sprang from the occipital region. It was smooth, transparent, fluctuating, very thin walled, and destitute of hair, save at the pedicle and about the hilus, where there was a rather abundant, long growth. The blood vessels could be plainly seen. The child, while small for its age, was otherwise apparently normal and seemed hearty. The knee jerks were present and sensation normal. The author discusses the general treatment of this condition and describes the operation he performed in detail.

5. Craniotomy.—Marx asserts his own conviction that the life of the mother deserves much more consideration than that of an unknown fetus. Craniotomy on the living child is therefore at times justifiable. The author considers in some detail the absolute and the relative indications for craniotomy. It is perhaps not possible to condense the author's arguments without misrepresenting him. The following quotation shows his general position: "When from an early rupture of the waters a version is impossible, the tentative use of typical or atypical forceps . . . might be of value. The application must not be persisted in too long, or be too powerful, for fear of doing injury to the fetus. If this be unsuccessful, the woman and child in good condition, and the patient in such environment that the outcome of an operation is reasonably certain, then and then only would a Cæsarean section be allowable. But all our discussions and inclinations will in nine cases out of ten receive their quietus by the ever familiar phrase you all know so well, 'Save my wife and destroy the child.' Is this not true? Discussion among scientific men at a meeting and heart to heart consultations at the bedside of the parturient woman are two widely different factors. One is theory, the other practice. Let not our positions change from one to the other; and in all sincerity it is my firm conviction that perforation has a place in midwifery; and as I grow older and more experienced in my own work I feel that the field for perforation and the allied operations is widening, and that for Cæsarean section, safe and life saving as it may be, is narrowing for cases essentially among our private clientele and private consulting work."

7. Cushion Diseases.—Potts asserts that by nature we were intended to sit on a hard surface and not on a soft cushion. He regards soft cushions as the chief ætiological factors in the production of the three following classes of disease:

The first of these has its seat in the integument, or beneath the integument of the perineal, and circumanal regions, and embraces such well known diseases as eczema simplex, eczema marginatum, intertrigo, erythema simplex, pruritus ani, and abscesses—tegumentary and subtegumentary. The second class has its seat in the mucous membrane, and submucous tissue, and embraces such disorders as simple urethritis, simple proctitis, anal ulcers, etc. The third class has its origin in the blood vessels and glands, and includes such diseases as hæmorrhoids, papillomata, adenomata, etc. The general treatment of each one of these affections is briefly considered.

AMERICAN MEDICINE

June 10, 1905.

1. The Treatment of Chronic Diarrhœa.
By REYNOLD WEBB WILCOX.
2. Observations Upon Amœbas Infecting the Human Intestine, with a Description of Two Species, *Entamoeba Coli* and *Entamoeba Dysenteriae*,
By CHARLES F. CRAIG.
3. Dysentery in Cook County Hospital,
By C. G. GRULEE and J. S. WELCH.
4. The Bacterial Element in Catharsis,
By GROESBECK WALSH.
5. The Lloyd Reaction for Morphine and Other Alkaloids,
By DANIEL W. FETTEROLF.
6. A Sign of Value in Splenic and Hepatic Disease,
By T. HORACE EVANS.
7. A Study of Reprints and Clinical Reports on Proprietary Medicines,
By ROBERT HESSLER.

1. Diarrhœa.—Wilcox emphasizes the fact that chronic diarrhœa is not always due to demonstrable changes within the alimentary tract. Symptomatic treatment is always a reproach, and for the present the best we can do is to divide diarrhœas into classes, based on their causation, and then treat them on general lines.

2. Observations Upon Amœbæ.—Craig ends his article with the following conclusions: (1) The intestine of man may be infected with two varieties of amœbas, one pathogenic (*Entamoeba dysenteriae*), and the other non-pathogenic (*Entamoeba coli*). (2) *Entamoeba coli*, the non-pathogenic variety, is found in 65 per cent. of the healthy individuals studied, and in 50 per cent. of individuals suffering from diseases other than dysentery, if a saline cathartic has been administered. (3) These organisms can be easily distinguished in both fresh and stained specimens. (4) They differ widely in their method of reproduction, and this is the most important method of distinguishing them. (5) *Entamoeba dysenteriae*, whether fed in milk or injected through the rectum, produces in kittens the typical lesions of amœbic dysentery as observed in man. (6) In kittens, *Entamoeba coli*, whether fed in milk or injected through the rectum, is absolutely harmless. (7) Neither feeding experiments nor rectal injections of fecal material or the bacteria occurring in such material produce any of the lesions of amœbic dysentery, unless *Entamoeba dysenteriae* is present.

3. Dysentery.—Grulee and Welch report the

1. Angina Pectoris.—Broadbent defines angina pectoris as pain in the cardiac region, chiefly behind the sternum, with radiation, most frequently down the inner aspect of the left arm to the elbow or to the hand. The pain is usually accompanied by a sensation of impending death, and the distinctive characteristic of true angina is that it is induced by exertion, more easily soon after food. Next to exertion in provoking an attack comes excitement. The effect on the circulation is increase of the blood pressure in the arterial system—this is the determining antecedent. The attacks are usually brief, subsiding with the cessation of exertion or with the inhalation of amyl nitrite, etc. Sooner or later sudden death occurs during, or at the onset of a paroxysm. But the pain may last for hours. During the paroxysm the one condition that seems to be always present is contraction of the peripheral arterioles. The pulse remains steady or becomes irregular, but rarely rapid. The most constant post mortem condition is more or less occlusion of the coronary arteries from a calcareous or atheromatous or sclerosed condition of these vessels with perhaps thrombosis. As a consequence to the obstruction to the blood supply, general or local degeneration of the walls of the heart is usually produced. As regards the causation the author holds that the condition of the heart walls is the dominant factor. Speaking generally, in all cases in which the attacks come on chiefly during repose, however severe or however closely they conform to true angina, the presumption is that they are spurious, false, or pseudoangina. The cases which most closely simulate true angina are those in which there is dilatation of the stomach. True angina is established when the coronary arteries are implicated. Mitral disease does not give rise to angina, nor does aortic disease of rheumatic origin. In acute aortitis, which is rare, there may be frequent anginoid attacks while the patient is lying in bed, if the mouths of the coronary arteries are blocked. In many cases of angina general arteriosclerosis is present, but the angina may manifest itself in a very early stage. The cases in which the prognosis is most unfavorable and in which least can be done for the patient, are those in which the physical signs are negative. The treatment resolves itself into that of high arterial tension. Such high tension is due to toxins in the blood, and these must be prevented from forming, and eliminated. Simplify the diet, regulate the exercise and supplement it by massage, and promote elimination by the use of water and the alkaline salts. Mercurial aperients and iodides definitely reduce arterial tension, and form the basis of the medicinal treatment. The direct vascular relaxants, amyl nitrite, etc., are invaluable for the relief of the paroxysms, but their influence is, of course, brief. Dilatation of the stomach may in cases of angina or heart disease, precipitate death. In illustration of these various points the author cites eleven cases of true and false angina.

2. Puerperal Infection.—McCann states that in puerperal fever the principal sites of infection

are: (1) the interior of the uterus, especially the placental area; (2) the cervix; and (3) the vagina and perineum. The commoner causative organisms are: (a) streptococci; (b) staphylococci; (c) bacillus coli communis; (d) gonococci; and (e) various putrefactive organisms. Two principal varieties of puerperal fever may be distinguished—wound intoxication and wound infection. The former is produced by organisms growing in dead matter, and producing toxins which are absorbed. Under wound infection are included the severe and fatal forms of the condition, the vast majority being due to streptococcal invasion. The infection spreads from the wound—(1) by the blood vessels producing thrombophlebitis, pyæmia, and septicæmia; and (2) by the lymphatics producing suppurative metritis (metritis dissecans), puerperal parametritis, perimetritis, and peritonitis. In putrid endometritis the interior of the uterus should be thoroughly cleaned out under an anæsthetic, puerperal ulcers wherever situated should be touched with tincture of iodine or pure carbolic acid, and the vaginal canal swabbed out carefully with corrosive sublimate. Rubber gloves are of great service. In most cases the finger is able to remove any retained products and no instrument is required. If curetting is attempted, a blunt instrument should be used and with the greatest care. Ergot is helpful in promoting uterine involution. In septic endometritis the organisms have already penetrated deeply into the uterine muscle and here the curette should certainly not be used. Careful swabbing of the interior of the uterus is to be preferred to douching. Up to the present time the results obtained from the employment of serum have been disappointing. In the treatment of puerperal infection it is necessary to maintain the patient's strength by means of the administration of a fluid, easily digested diet, and, above all, by the free administration of alcohol in large doses which are well borne in this disease. Quinine may still be relied upon, but it should not be given in very large doses. Calomel is also of great value. For the relief of pain some form of opium may be required. The presence of a collection of pus in the pelvis calls for prompt surgical treatment.

4. Pneumococcal Sore Throat.—Pasteur reports a fatal case of pneumococcal angina occurring in a boy, aged three and a half years. The prominent symptoms were sore throat with great pain on swallowing, and high fever. There was no laryngeal implication. Although cultures were negative diphtheria antitoxine was given, but without any effect. The patient grew steadily worse, and a gray gangrenous slough involved the uvula and palatal arches, and the patient died on the twenty-second day of the disease. Cultures *post mortem* showed the pneumococcus in large numbers. The condition has not received the attention it deserves, although it has been recognized for many years. The membranous form may closely simulate diphtheria. Of diagnostic significance are the sudden onset, often with a rigor, the severe initial symptoms, and the sharp

rise of temperature. The disease tends to run a short course—two or three days. The erythematous form of the affection is likely to be mistaken for scarlatinal angina.

5. "Plummer's" Bodies.—Farmer, Moore, and Walker have found a remarkable resemblance to exist between the so called Plummer's bodies of malignant growths and certain normal constituents of reproductive cells of animals. Plummer's bodies, which are found in the younger or growing regions of cancerous growths, are vesicles, consisting essentially of a fairly well defined wall containing a clear space in which is suspended a small darkly staining granule. They lie in the cytoplasm of the cancer cell and usually in close proximity to the nucleus. They have been commonly regarded as peculiar to the cancer cells, but the authors' investigations indicate that there are good grounds for reconsidering the whole position, and they suggest that a parallel between these bodies and certain vesicular structures occurring regularly in the gametogenic cells may be found to hold good.

6. Acute Aortitis.—Broadbent reports a fatal case of acute aortitis occurring in a man, aged forty-five years. When seen he complained of pain in the chest. The pain grew worse and began to radiate down the left arm, the pulse became soft and the heart's action weak. The patient died suddenly after being admitted to the hospital. At the autopsy the most striking feature was the bright red color of the aorta both inside and outside. The aortic valves were competent, but were thickened and atheromatous. The mouths of the coronary arteries were almost completely occluded. This was an acute inflammation attacking an aorta already damaged by atheroma, and the cause of death was the blocking of the coronary arteries. The duration of the disease from the first onset of cardiac pain was only seventeen days. There was no degeneration of the heart muscle.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of Thursday, April 6, 1905.

(Concluded from page 1192.)

The President, Dr. RICHARD C. NORRIS, in the chair.

Dr. NOBLE said he had never operated in one of his own cases for obstruction of the bowel a long time after a previous operation. He was told of one patient that had died of obstruction in a hospital. He had operated in a certain number of cases of septic peritonitis with so called obstruction, and all the patients had died. While he did operate in these cases, he always felt that the patients were going to die and they always had died. He doubted whether anything was gained by opening the abdomen again in a few days after an operation when there was septic peri-

tonitis. The more he saw of secondary operations done within a week after the primary operation, the less faith he had in the value of the procedure to the patient. So far as the hospital was concerned, there was the risk of infecting the operating room. Therefore, if it was of no advantage to the patient and was an injury to other patients, he thought it further objectionable to reopen the abdomen.

Dr. HIRST contributed three cases of interest to this list. He operated some years ago in a curious case of acquired atresia of the vagina and pyelometritis. There was a large abscess in the vaginal and uterine cavities above the point of atresia, with perforation of the vesicovaginal septum, suppurative cystitis, and infection of the kidneys. He found on examination a row of silver sutures across the vagina which had been inserted three years before in a hospital in Philadelphia in an operation for prolapse. The operation had cured the prolapse, but had caused the acquired atresia. The easiest way to deal with the condition was to remove the uterus and to close the vesicovaginal fistula from above. The woman was relieved of her symptoms and left the hospital in good condition. Nine months later she had obstruction and went to another hospital, where she was operated on and died. He was told by the operator that the point of obstruction corresponded with one corner of the stump of the supravaginal hysterectomy.

In another case he operated more than a year after the first operation, by Dr. Beyea, who had removed one tube and ovary. The woman was brought into the Orthopaedic Hospital with the symptoms of partial obstruction. There was a large and distended loop of gut on the right side in the region of the caput coli. There were great pain and sensitiveness on pressure over this distended loop of gut. There was constipation almost to complete obstruction. He opened the abdomen and found a fan-shaped sheet of adhesions spreading from the appendix around the colon, but having nothing to do with Dr. Beyea's operation. At one point four inches above the caput coli there was constriction of the ascending colon, so that the woman had partial and increasing obstruction of the large bowel. The bowel was released and the symptoms disappeared after separation of the adhesions. The abdomen became flat, the fever subsided, the pain disappeared, the bowels moved easily, and the patient was now well.

The third case was very interesting. Dr. Kelly had published a full page illustration of it in his recent book on appendicitis. The patient was taken to the Howard Hospital one evening in a cab, in a very serious condition, for what Dr. Musser and Dr. Hirst thought to be fulminating appendicitis. So sure were they of the diagnosis that a lateral incision was made, but to their chagrin they found only a circumappendicitis of very acute type, the chief trouble being an acute salpingitis with pus dripping out of the abdominal ends of both tubes. Dr. Hirst removed the appendix and both tubes through the lateral incision and closed the wound without drainage. The

woman made a good recovery. After going home, at the end of three or four weeks, she was slowly attacked with the symptoms of increasing obstruction, which continued over a period of five or six weeks. At length the condition was unmistakable and Dr. Hirst recommended reopening the abdomen. At the request of the family, Dr. Kelly was asked to witness the operation. Dr. Hirst found a slight adhesion between a point of the omentum and the site of the appendicular stump. It was scarcely an eighth of an inch broad, but the omentum had been pulled out, making a small circular orifice through which twelve or fourteen inches of gut had prolapsed. This was quite dark in color and badly constricted. The woman had had vomiting, constipation, and distention of the abdomen and was rapidly passing into a serious condition. The obstruction was easily relieved, whereupon the symptoms all disappeared and the woman made a perfect recovery.

Dr. Hirst thought these cases showed the possibility of intestinal obstruction late after abdominal section. In the earliest of these cases the operation was done about nine weeks after the first operation, and in the latest nearly two years.

Dr. SHOEMAKER said, in answer to Dr. Noble's question about the dry treatment of the plastic cases, that he found his cases did distinctly better. Not that he had any special trouble, but he always felt dissatisfied about the nurse's putting in the irrigation tubes when he had done extensive plastic work, especially on the anterior wall, and in sphincter cases.

In reference to late postoperative obstruction, he recalled a case in the Presbyterian Hospital, not in this series, but which fortunately came back to him one year after operation for gonorrhœal salpingitis. He had done excision of both tubes and one ovary, and was highly gratified at the second operation to find that the remaining ovary was absolutely normal in appearance, and that the adhesions had all disappeared, except one. The symptoms of acute obstruction were due to one strong, narrow adhesion band now crossing the descending colon. This was released, the symptoms disappeared, and the patient recovered perfectly.

The adhesions in these bad cases undoubtedly disappeared if the focus was removed, but there might occasionally remain a band long enough to produce mechanical obstruction. He had had some interesting experiences in observing the disappearance of adhesions. One of the cases included in this one hundred was that of a woman under the care of a surgeon near Pittsburgh, who had had several attacks of appendicitis in which pus had escaped spontaneously into the bowel. She had then refused an operation. After one of her attacks pus had appeared on the surface within the line of the pubic hair, giving rise to a temporary fecal fistula. At the time of his operation all these anterior adhesions had disappeared and no trace of this fecal fistula remained. He was able to save her by taking out the appendix and doing away with the point of communication with the bowel posteriorly.

Book Notices.

Elements of Anatomy and Physiology, Especially Adapted for Nurses. By W. BERNARD SECRETAN, M. B. (Lond.), F. R. C. S. (Eng.), L. R. C. P. London: The Scientific Press, Limited, 1905. Pp. xvi-74. (Price, 2s.)

The author has sought to prepare a manual that will embrace such facts in anatomy and physiology as are required by the average hospital nurse, with an avoidance of all unnecessary and confusing matter. To one familiar with the superfluous detail in the works usually used by students of nursing this book will seem meagre and inadequate, but it contains all the facts regarding these subjects that are essential for the nurse's information and for the intelligent discharge of her duty.

The General Practitioner as a Specialist. A Treatise devoted to the Consideration of Medical Specialties. By J. D. ALBRIGHT, M. D. Third Edition, Revised, Enlarged, and Illustrated. Philadelphia: Published by the author, 1904. Pp. 367.

The fact that this book has reached a third edition indicates that it has found a number of readers, and we trust that they were professional men rather than laymen, who hoped by the instruction given to find an easy way to masquerade as specialists. In the hands of men who have been properly trained the treatment advised may be of some value, but those who are untrained, or who do not appreciate the necessity of a detail that the author does not give, are likely to do more or less serious injury to patients subjected to the treatment recorded.

Recurrent Effusion into the Knee Joint After Injury, with Especial Reference to Internal Derangement, commonly called Slipped Cartilage. An Analysis of 750 Cases. A Clinical Lecture delivered at St. George's Hospital, by Sir WILLIAM BENNETT, K. C. V. O., F. R. C. S., Senior Surgeon to St. George's Hospital, etc. With Eleven Illustrations. Reprinted, after revision, from the *Lancet*. London: Longmans, Green, & Co., 1905. Pp. 29.

This lecture, which was published in the *Lancet* last January, is a consideration of 750 cases of recurrent effusion into the knee joint caused by injury or constitutional conditions. So extensive an experience is unusual. Where an operation was needed to remedy defective power of movement or to relieve pain, the author has never found the transpatellar operation necessary, the lateral longitudinal incision being sufficient to give access to the joint. The result in all but two of the cases was perfect.

Miscellany.

Primary Lesion of the Tonsil.—The extragenital primary lesion almost always presents difficulties in diagnosis to the trained dermatologist, ever on the alert to the suspicion of syphilis, and becomes especially grave for the patient and his or her surroundings when the lesion is upon the tonsil where the practitioner either ig-

noses the possibility of syphilis or where, as in the case described by Dr. D. W. Montgomery in his paper in this issue (*Journal of Cutaneous Diseases*, for May, 1905), a benign staphylococcal infection of the tonsil simulated a chancre. That among extragenital lesions an initial lesion of the tonsil is not rare is shown by the statistics of Neumann¹ who reports ten cases of chancre of the tonsil out of a total of 207 cases of extragenital infection. Neumann's observations extended over the period 1880 to 1901, and during this time 4,634 cases of primary lesions were treated.

The writer has observed two cases of chancre of the tonsil in hospital and dispensary practice. One case, in a young girl, had been operated in two weeks before and the satellite group of enlarged cervical glands had been removed under the wrong diagnosis of tuberculous glands of the neck.

The other case was in a man convalescent from typhoid fever in a hospital who presented a chancre of the left tonsil, general adenopathy, and a maculopapular syphilide. Methods of infection in the two cases were not ascertainable.

Vincent's angina is another condition which may cause doubt in diagnosis, and it must be remembered that the finding of the fusiform bacilli and spirochetæ of Vincent does not exclude the presence of syphilis, as we have observed in three cases, two of women and one of a man, all of whom presented thick, dark brown patches on the tonsils, in which a microscopical examination revealed the presence of Vincent's bacilli and spirochetæ, while other well marked signs of syphilis were present.

Diphtheria, of course, is to be considered in the diagnosis, and while cultures would furnish positive evidence, the coexistence of syphilis must be kept in mind also, as the writer has had under treatment a physician who became inoculated upon the index finger with syphilis while inserting an intubation tube into the larynx of a child suffering with both diseases.

G. Nobl,² after calling attention to the great resemblance between syphilitic lesions of the mucous membranes and mucous processes of other ætiology, such as catarrhal angina, follicular inflammation, ulcerative changes, acute streptococcal infections, mercurialization, ulceromembranous affections, Vincent's angina, aphthous patches, etc., records two cases of primary lesions of the tonsils in which, under a wrong diagnosis of tonsillar abscesses, both cases had been operated in by crucial incisions with resulting necrosis and suppurative breaking down of the tonsils, and also of the satellite glands, with unusually severe specific exanthemata and other symptoms. This incision of primary lesions under a wrong diagnosis, he maintains, opens the way for severe mixed infections to complicate the prognosis and all haste in advising operative interference in a suspicious lesion should be guarded against.

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending June 7, 1905:

- ACHENBACH, J., Pharmacist. Granted leave of absence for sixteen days from June 13th.
- BEAN, L. C., Acting Assistant Surgeon. Granted leave of absence for three days from June 8th.
- CLARK, TALIAFERRO, Passed Assistant Surgeon. Granted leave of absence for three days from June 7th, under paragraph 191 of the regulations.
- KERR, J. W., Passed Assistant Surgeon. Granted leave of absence for one month from June 13th.

MASON, W. C., Acting Assistant Surgeon. Granted leave of absence for five days from June 26th.

McCONNELL, E. F., Acting Assistant Surgeon. Relieved from duty at Nuevitas, Cuba, and directed to proceed to New York, and report to Surgeon G. W. Stoner, Ellis Island, for duty.

OAKLEY, J. H., Passed Assistant Surgeon. Detailed as inspector of unseizable property at the United States Marine Hospital, Port Townsend, Wash.

PORTER, J. Y., Sanitary Inspector. Granted leave of absence for seven days from June 20th.

RANSOM, S. A., Acting Assistant Surgeon. Granted leave of absence for two days from May 3rd.

SALMON, T. W., Assistant Surgeon. Granted leave of absence for five days from June 4th, under paragraph 191 of the regulations.

SAWTELLE, H. W., Surgeon. Relieved from duty at Purveying Depot, New York, and directed to proceed to Washington, D. C., for special temporary duty.

SPRATT, R. D., Assistant Surgeon. Relieved from duty at New Orleans, La., and assigned to duty at Louisville, Ky., effective June 15, 1904.

STONER, G. W., Surgeon. To proceed along Canadian border as far as Sault Ste. Marie, Mich., stopping at intermediate points, especially Quebec, Montreal, Niagara Falls, and Detroit, on special duty.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending June 10, 1905:

BARTLETT, C. J., First Lieutenant and Assistant Surgeon. Reported for temporary duty as attending surgeon and examiner of recruits, San Francisco, Cal.

BLANCHARD, R. M., First Lieutenant and Assistant Surgeon. Left Fort Thomas, Ky., on ten days' leave of absence.

BROOKE, ROGER, JR., First Lieutenant and Assistant Surgeon. Having arrived at San Francisco, Cal., from Manila, P. I., will report to the commanding officer, Fort Bayard, N. M., for duty at the General Hospital.

BRUNS, EARL H., First Lieutenant and Assistant Surgeon. Assigned to duty at the Sequoia National Park, Cal., relieving Assistant Surgeon Kiersted.

CHIDESTER, W. C., First Lieutenant and Assistant Surgeon. Ordered to accompany Companies A and B, First Battalion Engineers, from Fort Leavenworth, Kan., to San Francisco, Cal.; on completion of this duty to revert to status of leave of absence.

CRAUTREE, GEORGE H., First Lieutenant and Assistant Surgeon. Ordered to proceed from Fort Jay, N. Y., to Fort Monroe, Va., for duty in connection with the joint Army and Navy exercises.

DALE, FREDERICK A., First Lieutenant and Assistant Surgeon. Relieved from duty at the United States Army General Hospital, Washington Barracks, D. C., and ordered to Fort Walla Walla, Wash., for duty. Granted two months and fifteen days' leave of absence.

GIENER, HERBERT C., First Lieutenant and Assistant Surgeon. Assigned to duty at the Yosemite National Park, Cal., to relieve Major Reynolds, surgeon.

PORTER, R. S., First Lieutenant and Assistant Surgeon. Left Fort Niobrara, Neb., on leave of absence.

POWELL, JUNIUS L., Major and Surgeon. Left Fort Hamilton, N. Y., on ten days' leave of absence.

REILLY, JOHN J., First Lieutenant and Assistant Surgeon. Relieved from further duty at Jackson Barracks, La., and ordered to Fort Slocum, N. Y.

RENO, WILLIAM W., First Lieutenant and Assistant Surgeon. Relieved from temporary duty at Washington Barracks, D. C., and from duty with troops at Saunders's Range, Md., and ordered to return to his station, Fort Meyer, Va.

REYNOLDS, F. P., Captain and Assistant Surgeon. Relieved from duty at Yosemite National Park, and to return to station at Presidio of San Francisco, Cal.

ROBERTS, WILLIAM, First Lieutenant and Assistant Surgeon. Relieved from temporary duty at Fort Greble, R. I., and ordered to return to Fort Hamilton, N. Y.

SHIMER, IRA A., Captain and Assistant Surgeon. Left Washington, D. C., *en route* to Ancon, Isthmian Canal Zone, for duty with the Isthmian Canal Commission.

SMITH, HERBERT M., First Lieutenant and Assistant Surgeon. Relieved from further duty at Fort McDowell, Cal., and ordered to the United States Army General Hospital, Presidio of San Francisco, Cal., for duty.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending June 10, 1905:

BISHOP, L. W., Passed Assistant Surgeon. Detached from the Naval Museum of Hygiene and Medical School, Washington, D. C., and ordered to the *Dubuque*.

EYTINGE, E. O. J., Assistant Surgeon. Ordered to the Naval Hospital, New York, N. Y.

FARWELL, W. G., Assistant Surgeon. Detached from the Naval Hospital, New York, N. Y., and ordered to the *Brooklyn*.

MAVERS, G. M., Assistant Surgeon. Ordered to Washington, D. C., for examination for promotion, and then to await orders, June 19, 1905.

MURPHY, J. F., Assistant Surgeon. Detached from the *Dubuque* and ordered to continue duties on the *Hancock*.

STITT, E. R., Surgeon. Detached from the Naval Museum of Hygiene and Medical School, Washington, D. C., and ordered to the Naval Hospital, Canacao, P. I.

The following passed assistant surgeons have been ordered to report to the president of the Naval and Medical Examining Boards, for examination for promotion, June 26, 1905, and then to await orders: F. L. BENTON, F. M. FURLONG, W. M. GARTON, J. F. LEYS, and J. C. THOMPSON.

Births, Marriages, and Deaths.

Married.

DYE-PERRY.—In Philadelphia, on Thursday, June 1st, Dr. Frank Hazzard Dye and Miss Jean Perry.

FARINGER—LEOPOLD.—In Germantown, Pennsylvania, on Wednesday, June 7th, Dr. Howard R. Faringer and Miss Gertrude E. Leopold.

LAZARUS—CAMP.—In Brooklyn, N. Y., on Tuesday, June 6th, Dr. George Frederick Lazarus and Miss Leslie Virginia Camp.

RAUTERBERG—HULLIKEN.—In Baltimore, Maryland, on Saturday, June 3rd, Dr. L. E. Rauterberg and Miss Meta Hulliken.

TAYLOR—REILLY.—In Philadelphia, on Wednesday, June 7th, Dr. Mervyn Ross Taylor and Miss Jeannette Reilly.

Died.

DONAVIN.—In Baltimore, Maryland, on Monday, June 5th, Dr. Matthew W. Donavin, in the sixty-seventh year of his age.

GETMAN.—In Oneonta, N. Y., on Tuesday, May 30th, Dr. Arthur D. Getman.

GILLISS.—In York, Pennsylvania, on Friday, June 2nd, Dr. Joseph A. Gilliss, of Baltimore, in the sixty-third year of his age.

GOODIN.—In Cincinnati, Ohio, on Wednesday, May 31st, Dr. William Isaac Goodin, in the sixty-ninth year of his age.

LIPPINCOTT.—In Campbell Hall, N. Y., on Wednesday, June 7th, Dr. De Witt G. Lippincott, in the forty-fifth year of his age.

MALONEY.—In Keene, New Hampshire, on Thursday, June 1st, Dr. William E. Maloney, in the forty-first year of his age.

ORR.—In New Orleans, Louisiana, on Monday, May 29th, Dr. Henry B. Orr.

PALMER.—In Warsaw, N. Y., on Sunday, May 28th, Dr. George Miles Palmer, in the sixty-eighth year of his age.

STREETER.—In Lake Forest, Illinois, on Sunday, June 4th, Dr. John William Streeter, in the sixty-fourth year of his age.

TAYLOR.—In Richmond, Missouri, on Friday, May 26th, Dr. James D. Taylor, in the seventy-first year of his age.

TWO CASES OF RARE CONGENITAL MALFORMATION.

By HERMANN FISCHER, M. D.,

NEW YORK,

ADJUNCT SURGEON, GERMAN HOSPITAL.

Congenital malformations and defects are, as a whole, not very frequently met with in this country and for the reason that the following two cases are unparalleled, I may be pardoned if I briefly describe them:

I. A CASE OF MENINGOENCEPHALOCELE OF UNUSUAL SIZE.

On April 17, 1900, I was called to Mrs. K., a primipara, to assist her in her confinement. When I reached the patient, the child was already born. After two vigorous uterine contractions the child had been expelled, the whole labor having lasted only two hours. The short time of labor in a primipara was certainly very unusual, but after an examination of the child's head was easily explained.

The whole head of the baby, a well developed boy, was much larger than normal and of an oblong shape. The scalp was covered with fine hairs. A caput succedaneum was absent. On palpation I found that the upper part of the head was soft, like a cystic tumor; no underlying bone could be felt. Five centimetres above the nasal process of the frontal bone, one could palpate a transverse bony ridge, indicated in the overlying soft parts, by a slight groove. This bony ridge extended all around the head. In its course backward it curved a little downward until it reached the level of the external occipital protuberance. This ridge marked the limit of the bony cranium. The appearance of the head was similar to that of a skull, of which the bony vault had been removed at autopsy. The tumor itself was of a soft cystic consistence. True fluctuation could not be elicited. Pulsation was absent. If the child cried the tumor became more tense and elastic. Pressure upon it caused the child to show uneasiness, but no marked cerebral disturbances. Reposition of the swelling was impossible. The reflexes were normal. There was no paralysis of limbs or face. If the finger was inserted into the mouth, the child eagerly began to suck.

Transillumination of the tumor gave a negative result. The child was otherwise well developed.

We have to deal in this case with an unusual large defect in the formation of the bones which help to make up the roof of the cranium, with a prolapse of its contents. They are, however, covered by a well developed hairy scalp. There is also undoubtedly an hydrocephalus internus present, as shown by the cystic consistence of the whole mass.

The upper third of both frontal bones is missing. The two parietal bones are totally absent and the occipital bone is formed only as far as the external protuberance; its squamous portion being undeveloped. Of the two temporal bones, the petrous portion is well developed, whereas the upper third of the squama is wanting. The bones of the face are well formed. Examination for other defects is negative.

The unusual feature in this case is the position and the large size of the cerebral hernia. It takes up the whole upper portion of the skull and is almost twice as large as the face. The measurements of the head are the following: Measurement from the upper edge of the frontal bone to the edge of the occiput is ten and three quarter inches; from the external right to external left auditory meatus, ten and a half inches. The height of the frontal bone from glabella to the ridge is two inches. The height of the temporal bone from antitragus is one and a half inch on the right side and one and three quarter inch on the left.

The usual site of an encephalocele is at the sinciput or occiput. The encephalocele sincipitalis appears in front upon the forehead, directly above the nasal bone. In these cases the nasal processes of the frontal bones or parts of the frontal bones itself are wanting; or the encephalocele appears below the nasal bones. Then the defect is in the neighborhood of the foramen cæcum and the anterior portion of the ethmoidal bone. Furthermore, the nasal processes of the superior maxillary bones and the lacrymal bones may be missing and the cerebral hernia protrudes externally into the nasal cavity or laterally into the orbital cavity. The encephalocele occipitalis appears either above or below the protuberance. In the latter case, the defect in the bone extends frequently into the foramen magnum or even

into the bodies of the vertebræ, producing a condition known as craniorrhachischisis. Those cerebral hernias that occupy the sagittal suture or the lateral fontanelles are not frequent. Those that make their way through the pharyngeal canal close to the body of the sphenoid bone into the pharyngeal cavity are very rare.

As to the coverings of cerebral hernias, we see in our case a well developed scalp covered with hair, which, however, appears somewhat thinned out. When the child cries the scalp becomes glossy in appearance through increased tension. Little, of course, can be said with certainty about the condition of the meninges. We can assume, however, that through pressure and tension atrophy has taken place and that the different layers have become adherent one to another.

The diagnosis was not a difficult one, because the enormous defect in the cranium, which was easily palpable, led to the correct interpretation of the condition. In other cases, however, where the tumor is of a small size and where the defect in the bone is not easily palpable, the diagnosis may present a good deal of difficulty, especially in adult persons. Important in such cases is the determination of the presence of the tumor at birth, the demonstration of an opening in the skull, the sinking in of the tumor at quiet breathing and the appearance of symptoms of cerebral compression when pressure upon the mass is exerted.

Concerning the ætiology of these tumors the opinion of authors differ. St.-Hilaire, Foerster, and Panum assume as their cause a hydrocephalus of the primary vesicles of the brain. Daresté and Perls, however, consider that the pressure of the cephalic end of the amnion upon the growing head is responsible for the arrest of development. In our case the cause of the malformation is probably a primary agenesis of the bones that are normally destined to form the vault of the cranium. It seems to me hardly rational to assume that external pressure upon the head was responsible for the arrest of development of the bones. If such pressure had existed for any length of time during the embryonal stage, we undoubtedly would see some signs of it on the external coverings, in form of scars or atrophy of the scalp. No such symptoms are found. The theory of St.-Hilaire, Foerster, and Panum seems to be more plausible for the case in question. Heredity does not seem to play any ætiological part in our case. Father and mother are both healthy; neither of them is infected with lues. Other malformations have not happened among the nearer relatives of the two. Two years after the birth of this malformed boy, the mother gave birth to well developed twins, two girls. Both died when a few months old, one from a bronchopneumonia, the other in consequence of an acute osteomyelitis of the tibia. The prognosis in such a case is of course extremely bad. Therapeutically, we are powerless.

The interest that this case presents is increased through the unexpected longevity of the little pa-

tient. When a few months old the mother took the child to one of our hospitals, where an incision was made into the mass. I have seen the child off and on for four years. It had to be fed with the bottle, and in spite of the unfavorable surroundings in which it had to live was bodily thriving. In the summer of 1903 it passed through an severe attack of cholera infantum. When I saw the child in December, 1903, it presented the following condition:

Anæmic, poorly developed boy. The tumor of the head has grown to an enormous size and was covered with unusually thick hair. The mass fluctuated distinctly, was very soft. Alteration in its consistency had not occurred. The old scar of the incision in the scalp had become very much thinned out by the intracranial pressure and looked like parchment paper. Handling of the tumor seemed to annoy the child a good deal, as it cried violently as soon as its position was changed. The measurements taken over the highest point of the mass from the glabella to the external protuberance of the occiput was twenty-five and a half inches; from the antitragus of the left ear over the tumor to the right at the corresponding point it measured twenty-three inches. A year ago the child showed an internal strabismus on both eyes, which, however, passed off after some time. There was no paralysis of ocular muscles. An ophthalmoscopic examination that was kindly done by Dr. Wolff revealed the existence of an atrophy of both optic nerves. The child was blind. The hearing was intact, for the child had learned to recognize the voice of its mother. The right arm was held in slight spastic flexor contraction. The elbow joint, the wrist joint, and the finger joints were flexed. The thumb was flexed and adducted. This arm was very little moved by the child, although a complete paralysis did not exist. The spasm of the flexor muscles could be easily overcome. The left arm was moved about freely. Both legs showed the same spastic condition as the right arm. The symptoms were here more pronounced on the right side. Babinsky's phenomenon is present in the right foot. The muscles of the thigh and calf were very much atrophied. No clonus; reflexes were exaggerated. If the child kept the feet at rest they showed the condition of *pes equinus*, owing to the weakness of the dorsal flexors of the foot. The boy had never learned to speak or to walk. I saw the child again on October 4, 1904. His aunt told me, that during the summer the boy had had two convulsions. His whole body become very stiff, and he was very cyanotic. His condition was otherwise unchanged.

The fact that there have not developed any serious symptoms of pressure upon the brain is not difficult to explain. We know through the experiments of Grashey, Bergmann, Cramer, Cushing, Kocher, and others that the clinical picture of cerebral compression is instituted as soon as the extravascular pressure through any reason is raised above the intravascular pressure in the venous blood channels of the brain. The first requisite for such an accident, of course, is a cavity closed in by rigid and unyielding walls. This

condition is wanting in our case. If the extra-vascular pressure through increase of hydrocephalic fluid rises, the soft parts, closing in the brain, give way and thus shield the brain vessels from dangerous compression.

II. A CASE OF PEROBRACHIUS AND PERODACTYLISM.

The second case of malformation, that I am about to describe is that of a Polish Jew. The case was sent to me for an x ray picture through the kindness of Dr. Bachmann and Dr. Hotzen, of the German Dispensary. The patient is a man 62 years of age. He came to the dispensary in order to be treated for a left sided paralysis of the arm and leg, the consequence of an apoplectic stroke he sustained two years ago. He presents the rare malformation known as perobrachius and perodactylism.

Both humeri are well developed. There is a complete bony ankylosis of both elbow joints.

On the right side, the ulna is developed only to about two thirds of its upper portion. The radius of this side is much thicker than normal and much shorter. The carpal bones are only two in number. They represent according to their shape in the skiagram most probably the

FIG. 2.—External appearance of child in Case 1.

os trapezium and trapezoid, so that the radiocarpal joint is formed by these two bones and the lower end of the radius. The thumb and index finger are perfectly shaped, whereas the other three fingers are missing. On the left side the defect of the ulna is more pronounced than on the right. Here only the upper third of the ulna is developed in form of a short stump. The radius of the left arm is shorter and thicker than that of the right arm. There is no attempt at forming a radiocarpal joint at all, but the first metacarpal bone articulates with the carpal end of the

FIG. 1.—Skiagram of Case 1.

FIG. 3.—Case 2; skiagram of right hand.

radius forming a radiometacarpal joint. On the volar surface of the joint the skiagram shows two carpal bones which, however, do not take part into the formation of the joint. What these two bones are cannot be determined with certainty. The well developed first metacarpal bone articulates with the first phalanx. In place of the terminal phalanx there are three small bones, one evidently the poorly developed terminal phalanx, articulating at the radial side of the first phalanx. On his ulnar side, however, are two poorly developed bones, articulating end to end. Besides this we notice upon the ulnar side of the distal articular surface of this bone (first phalanx) a small

FIG. 4.—Case 2; skiagram of left hand.

hooklike process. I consider this process to be the intimation of a third phalanx that did not fully develop. On the left side we have therefore the condition of perodactylism combined with syndactylism. Another interesting point in our case is that the ulna is the subject of arrest of development, whereas usually in congenital malformations of the forearm the radius is the one affected.

As to the usefulness of his two arms with only three fingers, the man informs me, that he thought he got along just as well as other people with normally developed upper extremities. Before he had his apoplectic stroke he was a watch repairer, an occupation that certainly calls for a good deal of dexterity. But now, while his left arm is paralyzed, he earns his living by giving lessons in penmanship and acting as secretary to those in his Jewish community who are not able to write.

130 EAST SEVENTY-SIXTH STREET.

THE DEMONSTRATION OF THE FLAGELLA OF MOTILE BACTERIA AND A SIMPLE METHOD OF MAKING PHOTOMICROGRAPHS.*

By EDWARD W. DUCKWALL, M. S.,

PITTSBURGH, PA.,

MEMBER OF THE SOCIETY FOR THE ADVANCEMENT OF SCIENCE.
OF THE AMERICAN CHEMICAL SOCIETY, OF THE SOCIETY
OF AMERICAN BACTERIOLOGISTS, DIRECTOR AND BACTERIOLOGIST OF THE NATIONAL CANNERS' LABORATORY, BACTERIOLOGIST OF THE HEALTH DEPARTMENT, ASPINWALL, PA.

It affords me great pleasure to present a paper on this subject of staining flagellated bacteria. I have demonstrated the flagella on nearly all pathogenic bacteria, but my particular study has been with the non-pathogenic or saprophytic bacteria, which are associated with the spoiling of food products. This work is done under my direction in the Sprague cannery's laboratory, an institution founded and maintained for the food product industry. When making my reports each month to the *Canners' Journal*, I was impressed with the necessity of having specially attractive illustrations, and I believe that the motile bacteria should be represented in the illustrations just as they are naturally. The photomicrographs usually displayed in works on bacteriology do not as a rule represent motile bacteria as they should. I therefore took up the study of staining these organisms and endeavored to discover a method which would give good results with all kinds of bacteria and I made a comparative study of technique.

I have always obtained the best results with all species of bacteria, excepting the anaerobic, by streaking the surface of two per cent. agar in Petri dishes, and the streaked culture should always be made from the young growth in bouillon and never from an agar or gelatin transfer. I usually inoculate a tube of bouillon the night before, streak the surface of the agar early on the following morning, and then place the dishes in optimum temperature, so that I may get the most rapid growth possible. I find that two per cent. agar is preferable to that of less percentage, because the bacteria as a rule do not collect much debris from the culture media. Bacteria differ widely in the number and character of their flagella. Some are peritrichous, having large numbers growing out from all parts of the cell; some are lophotrichous, having a bunch of flagella at one end; some are amphitrichous, having a flagellum at either end; some are monotrichous, having a single terminal or polar flagellum. The flagella of different organisms vary in character; some are extremely fine, so delicate that they stain

with difficulty; some are long and wavy; others are short and may be almost straight. The anaerobic bacteria possess flagella which are extremely curly, and I could determine from the character of its flagella whether an organism was an anaerobe or an aerobe. Many motile bacteria produce spiral bodies which are termed "giant whips" by Novy; some of these will reach 100 inches in length.

I found that the methods for flagella staining described by the old authors had to be modified considerably in order to get good results. By constant practice and very hard work, often prolonged into the small hours of the morning, I finally succeeded in my efforts. I found there were six general classes of bacteria, each different from the other in its manner of growth, making it necessary to treat each class in a different manner. I divided the motile bacteria into six classes for staining purposes.

First, Bacilli which grow like the streaked culture of the typhoid, such as typhoid and colon.

Second, Bacilli which produce wrinkled or folded growths, such as *Mesentericus fuscus*.

Third, Bacilli which send out a thin, almost transparent growth over the surface of the agar, such as *Bacillus subtilis* and *Bacillus megatherium*.

Fourth, Bacilli which produce slime, such as *Bacillus vulgaris* and *Bacillus viscosus*.

Fifth, Bacilli which produce pigments, such as *Bacillus prodigiosus* and *Bacillus cyanogenes*.

Sixth, Anaerobic bacteria, such as *Bacillus tetani*, and the bacilli of oedema and symptomatic anthrax, etc.

FIG. 1.—*Bacillus Typhi Abdominalis*, multiplied 1,000 times.

MANNER OF MAKING SUSPENSIONS IN WATER.

(1) Bacteria resembling typhoid streak cultures have very young and actively motile bacteria on the periphery of the growth. From this the material is taken and transferred to a large drop or two of

* Presented to the Society of American Bacteriologists.

distilled water which has previously been boiled. The platinum loop should be made from very fine platinum wire, only about half the size of the loop used for general purposes. This fine loop will gather sufficient material without taking up any of the agar. The material usually clings tenaciously to the loop, but may be liberated by the aid of another platinum wire if care is exercised. The bacteria are then allowed to disseminate spontaneously throughout the drop of water, so that the finest specimens will swim to the outer edges from which the coverglass preparation is made. Bacteria which have few flagella and those whose flagella have been broken will remain near the centre.

(2) Preparations made from bacteria which produce wrinkled or folded growths are made before the wrinkled growth is formed. In order to get a good preparation from this group of bacteria the agar should be streaked in the morning and then carefully watched for the first appearance of growth and from this a satisfactory preparation can be made.

FIG. 2. *Bacillus Mesentericus Fuscus*, multiplied 1,500 times.

(3) The thin, transparent, spreading growth is one of the best for demonstrating flagella. This growth is almost invisible and is composed of very young and actively motile bacteria. In order to get a good preparation from this a curved platinum wire is used to gently collect the bacteria *en masse* and then the small loop is employed to make transfers to the distilled water.

(4) The slime producing bacteria are very difficult for the demonstration of flagella. The slime collects between the flagella and the mordant fixes the slime as well as the flagella, so that the stain completely covers the delicate organs of locomotion. I found that this slime could be precipitated by shaking a water suspension with chloroform. A very young growth of the organism is used and transfers are made to about 1 c.c. of distilled water in the test tube until the water is made very cloudy. The slime increases the cloudiness and this is neces-

FIG. 3. *Bacillus* of blueberries, multiplied 1,000 times.

sary in order to have a sufficient number of bacteria to make a fine preparation. This cloudy suspension is then shaken with chloroform, which seems to cut away the slime from between the flagella; then the coverglass preparation is made from the water above the chloroform.

FIG. 4. *Bacillus Mesentericus Vulgatus*, multiplied 1,200 times.

(5) Bacteria which produce pigments soluble in chloroform are treated in the same manner. Those whose pigments are soluble in water and not in chloroform are more difficult to stain. I usually hold the coverglass under the tap after fixing the preparation in the flame previous to adding the mordant. In this way much of the soluble pigment is removed.

(6) Good suspensions of anaerobic bacteria are the most difficult of all to obtain. Bacteria which

are imbedded in stab cultures do not make good preparations, because the agar and débris cling tenaciously to the flagella. It is extremely difficult to get a good surface growth of obligative anaerobes because it usually requires two or three drops of a young bouillon culture for surface inoculation and when the growth appears the surface is covered with the old, partially dissolved cells and free spores. Still, some very fine preparations can be made from the surface of the culture. The

FIG. 5.—*Bacillus Cyanogenus*.

best results are obtained as follows: The medium is two per cent. glucose agar in slants and the inoculation is made back of the slant between the agar and the wall of the tube. I slide the needle down back of the slant and let it fall forward; I introduce two or three drops of a young bouillon culture and then replace the agar. By excluding oxygen and maintaining a blood temperature for thirty-six hours, a fine growth of bacteria usually appears between the agar and the wall of the tube and beautiful preparations can be made from this. Many rods containing spores still retain a full equipment of flagella.

FIG. 6.—*Bacillus of tetanus*, multiplied 1,000 times.

CLEANING THE COVERGLASSES.

I prefer the No. 1 round coverglasses, which when new are covered with a thick, greasy substance quite difficult to remove. Coverglasses used for the demonstration of flagella must be absolutely clean, and this is a most important feature. For removing the grease they are covered with sulphuric acid and allowed to stand for one day. The sulphuric acid is poured off and they are then covered with potassium bichromate and allowed to remain in this for several hours. This acid is then poured off and the coverglasses are washed with distilled water and transferred to a jar containing absolute alcohol, where they remain until ready for use. A single coverglass is removed with clean forceps from the alcohol, transferred to a piece of clean, well washed linen and dried without touching it with the fingers. The coverglass is then taken in the forceps and passed several times through the Bunsen flame, so that every particle of fat or grease is removed, and it must appear clear and free from blemishes. Many coverglasses are lost after heating in the flame, particularly if there are any currents of cold air through the room, but since the perfect condition of the coverglass is so important the loss of two or three is immaterial.

FIG. 7.—*Bacillus of malignant edema*, multiplied 1,500 times.

PREPARATION OF THE STAINING AGENTS.

The fixing agent is mordant and the stain is carbol gentian violet or preferably carbol fuchsin.

The mordant requires for its preparation 2 grammes of desiccated tannic acid, 5 grammes of cold saturated solution ferrous sulphate (aqueous), 15 c.c. of distilled water, and 1 c.c. of saturated alcoholic solution of fuchsin. The tannic acid is dissolved in the water first, by the application of gentle heat; then the ferrous sulphate and then the alcoholic solution of fuchsin are added.

To these ingredients, I have always found it advisable to add a certain amount of sodium hydroxide,

a one per cent. solution, varying from $\frac{1}{2}$ to 1 c.c. The best grade of filter paper is used for filtering the mordant, and there should be left a heavy precipitate. After filtering the color of the mordant should be of a reddish brown hue, not clear but somewhat cloudy, and this mordant must be used within five hours after it is made; after that time it loses its staining power. This is indicated by its gradual clarification and darkened color. It gives the best results when strictly fresh, and accomplishes its work in a much shorter time, so that very little if any heating is required when it is placed on the coverglass preparation.

Carbol fuchsin.—Take about 1 gramme of granulated fuchsin (not the acid fuchsin), put it in a bottle, and pour over it about 25 c.c. of warm absolute alcohol. Shake vigorously, and let it stand for several hours before using. The carbol fuchsin is made by diluting the saturated alcoholic solution four or five times with a five per cent. solution of carbolic acid. Carbol fuchsin should be freshly made, heated and filtered before using.

METHOD OF PROCEDURE.

Every organism differs from other organisms in its manner of absorbing the stain, so that some experimental work is necessary to determine just how the stain should be applied. In a general way we proceed as follows: A small loop full of the clouded water, obtained as described in the first part of this article, is transferred to the coverglass and gently spread over as large a surface as possible. Care must be exercised in spreading the drop. I usually carry the drop around the surface without touching the glass with the loop. In this way the surface is moistened, and the loop does not tear off the flagella. A confluent spread does not give as good satisfaction as a streak spread with a small space between each streak. The finest specimens for photomicrography are obtained from the periphery of the streaks. The spreading must be done rapidly, because evaporation takes place very soon. After evaporation takes place, there should appear very thin films along the track of the loop. The preparation must be fixed in the flame so that the bacteria will not wash off during the staining, but the fixing must not be accompanied by too much heating, because the delicate organs of locomotion are easily burned off. The Bunsen flame should be about one inch high; the glass held by the forceps, preparation side up, is passed down on to the flame just once and instantly removed. The coverglass is then ready for the mordant, which is poured on, just enough to cover the surface without flowing over the edges. I find that the Cornet forceps are best suited for staining purposes, and if the coverglass is held just a short distance within the edge,

the mordant or stain will not run off. It usually happens that we are unsuccessful in demonstrating flagella, if the mordant runs off, or goes on the under side of the glass. During the steaming of the mordant, it is advisable to keep up a rotary motion in order to avoid too much precipitation. When the mordant is fresh, it requires only about one half to one minute to get sufficient staining. The mordant is completely washed off under the tap, and this is done pretty thoroughly; a small quantity of absolute alcohol is poured on to the surface and instantly washed off. The alcohol removes a great deal of the precipitation which is found in coverglass preparations, but considerable care should be taken to wash it off quickly and thoroughly, because it will remove the germs and flagella if it is allowed to act even for a short time. If the alcohol is thoroughly washed off, the water is removed by holding the glass edgewise to a piece of filter paper. If the filter paper is not clean, considerable dust and fibre will be carried up on to the coverglass, and if there is any danger of this, it is better to finally wash the coverglass off with the distilled water and shake off the drops which cling to the glass. Then cover the surface with a carbol fuchsin or carbol gentian violet. I find in nearly all cases, that fuchsin is better than violet, and gives less precipitation, but in some cases the gentian violet brings out the flagella more prominently. This must be fresh, however, and thoroughly washed off after staining. We allow the fuchsin to stand on the coverglass for about one half minute, being heated just sufficiently for a thin vapor to be visible. We then heat it so that steam is given off quite freely, but never until ebullition takes place. Care must be used when heating the stain, because it is not unusual to find that there is entirely too much precipitation and the flagella are burned off. It rarely happens that we get a coverglass which will be stained well all over. Usually we get only certain sections where the flagella stand out prominently, and the field is free from precipitation. Views sufficiently attractive for photomicrographing are rare. While the staining may be perfect, there will be some defects in the germs. Some may have lost part of their flagella, or there may be too much precipitation in the field, or the germs may be too close together or too scattered. Ideal views for photomicrography are few, and it is sometimes necessary to stain up several coverglasses before we get a fine view. During the staining with the mordant and dye a thin film is formed all over the glass. This must not be broken up by the application of too much alcohol if a clear field is desired.

Some writers advocate the idea of examining the coverglass preparations on the slide with a drop of water under the coverglass, before finally clearing

and mounting the specimen. I have been unfortunate in this procedure and on several occasions have lost some beautiful specimens on attempting to float off the coverglass with water after examination. It frequently happens that the germs will stick to the slide and pull off, leaving graves surrounded by beautiful bunches of flagella, so I make it a rule to mount my coverglass in xylol balsam, as soon as I have finished staining. I do this as follows:

I select very thin slides, pieces of glass about 3 inches long and 1 inch wide, perfectly clear, and having no blisters. Having thoroughly cleaned the slide, I heat it over the flame to drive off moisture, and place in the centre a small drop of xylol balsam (which is Canada balsam dissolved in xylol, and comes in collapsible tubes). After thoroughly drying the water from the coverglass after staining, I pour pure xylol all over the surface, and immediately touch the edge to clean filter paper, and then drive off the xylol with heat. It is absolutely necessary to have the coverglass free from moisture before applying xylol (a refined benzin), otherwise a hazy appearance will be imparted to the preparation, spoiling it for microscopical purposes. After clearing with xylol and drying, the drop of balsam is heated gently and the coverglass, preparation side down, is pressed on to the slide so that the balsam is spread out in a thin layer between the two pieces of glass, the preparation thus being, of course, protected from injury. The method for the demonstration of the flagella of different organisms varies, as we have said. The differences which I have noticed have been in the length of time allowed for staining with the mordant and the fuchsin; also the amount of one per cent. sodium hydroxide. Great success is achieved only by careful and patient study of each organism. It is not a difficult matter to demonstrate the flagella of most motile organisms, but to get beautiful preparations is a study and requires great care in every step of the work.

SUMMARY.

Culture to be made on two per cent. agar from young growth in bouillon.

Suspensions in water to be made according to nature of organism.

Coverglasses to be absolutely clean.

Mordant to be used only when fresh.

Dye to be made fresh and used while warm.

Spread on coverglass not to be confluent.

Fixing to be done without injury to flagella.

Staining to be done without overheating.

Washing with alcohol and water without breaking the film.

Clearing with xylol after thorough drying.

Mounting in xylol balsam without previous examination.

A SIMPLE METHOD OF MAKING PHOTOMICROGRAPHS.

A large, cumbersome apparatus is unnecessary. The camera is about twice as long as the ordinary four by five inch camera, and the photomicrographs are taken with the camera in a horizontal position. It must be a steady apparatus and the microscope stand should be substantial and with the cone fine adjustment. Much depends upon the objective. In order to get negatives showing a flat field with clean definition I have used nearly all kinds of objectives, but have found none equal to the $\frac{1}{12}$ oil immersion objective and No. 6 compensating eye piece made by the Spencer Lens Company. The best plates are the isochromatic or orthochromatic swift plates, which are corrected for colors. I have found the acetylene radiant preferable to gas, oil, or electric light. It is slower than electric light, but brings out all details with wonderful nicety. The only screen I ever use is green glass. Printing from the negatives on glossy velox brings out the best detail. The glossy velox is then ferroplated, which makes a beautiful photograph.

McGill University, Montreal, Canada, has graduated the following from the medical faculty:

A. R. Alguire, of Cornwall, Ont.; J. A. Briggs, of New Westminster, B. C.; F. F. Brown, of Cornwall, Ont.; H. C. Burgess, of Sheffield Mills, N. S.; H. A. Chisholm, B. A., of Lindwood, N. S.; E. L. Connor, of Berlin, Ont.; W. J. W. Costello, B. A., of Montreal; C. F. Covert, of Montreal; A. Cumming, B. A., of Scottsburg, N. S.; B. H. Dougan, of Hampstead, N. B.; W. H. CLINICAL EXPERIENCE WITH ANTI-TOXINE, AND THE ADVANTAGES OF LARGE DOSES.

BY LOUIS FISCHER, M. D.,

NEW YORK.

VISITING PHYSICIAN TO THE WILLARD PARKER AND RIVERSIDE HOSPITALS, ETC.

(Concluded from page 1211.)

RASHES.⁶

The following series of rashes was observed at the Willard Parker Hospital:

Animal.	No.	Serum.	Number injected.	Rashes.	Character of rash.
Horse A.	234	Red serum.	19	4, or about 21 per ct.	Morbilloform, 1 Erythematous, 1 Urticarial, 2
Horse B.	246	Yellow serum.	33	11, or about 33 per ct.	Erythematous, 1 Urticarial, 1 Scarlatiniform.

Time at Which Rashes Appear.—Rashes usually appear between the fifth and seventh days after the injection of antitoxine. The size of the dose injected does not vary the intensity, form, or the time of appearance. In one child injected with 25,000 units, the rash lasted about six hours. In another child injected with 16,000 units, a rash appeared which lasted eight hours. The average duration of the rash is about three days. In one case the rash persisted as long as twenty-two days, while in another case the rash lasted but six hours.

In some cases two distinct rashes can be found which will correspond on two different days with injections given the first and second days of the illness. For example, if a child was injected on the first and on the third day of the month, one rash may appear on the seventh and another on the ninth of the month.

Preeruptive Fever.—Before an eruption appears there is usually a sudden rise of temperature which remains until the rash appears and gradually declines with the fading of the eruption. This is an important point, and should be remembered in suspecting complications during the course of diphtheria. Exceptionally a rash may appear without febrile exacerbation, as in the following case:

Eva L., 3 years 5 months old, was admitted to the Willard Parker Hospital October 29, 1904. There was a slight exudate on the tonsils and a severe laryngeal stenosis with croup. October 29th, received 5,000 antitoxine units; October 30th, 5,000 units. In all, 10,000 units were injected. The stenosis required intubation. The tube was removed forty-eight hours later. As no laryngeal stenosis reappeared, the tube was not required. There was a slight exudate visible when the child was extubated, but all evidence of this disappeared on the fifth day.

November 1st, an erythematous rash appeared, diffuse, almost covering the entire body. In this

case there was an exception to the usual rule, in so far as there was no preeruptive temperature. The temperature remained normal throughout the entire eruption.

Morbilloform Rash Following Antitoxine.—Lizzie F., 5 years old; admitted to the Willard Parker Hospital September 27, 1904. Was ill seven days before admission. There was a slight exudate on both tonsils. September 27th, received 5,000 antitoxine units; September 28th, 4,000 units; October 4th, had a temperature of 102°. Later a morbilliform rash appeared on the face, chest, abdomen, back, and extremities (a universal rash).

October 5th, temperature, 100°; October 11th, rash fading; October 12th, abdomen free.

FIG. 4.—Morbilloform antitoxine rash, lasting twenty-two days.

The rash appeared six days after the last injection, or seven days after the first injection. It

FIG. 5.—The same; another view.

I am indebted to Dr. Binford Thorne for assistance with this compilation.

persisted twenty-two days, and was confined chiefly to the arms and legs. The circulation of the child was very poor. No evidence of the disease could be seen in the throat after four days, so that the child was practically well. No complications followed. The membrane did not extend. The child left the hospital in excellent condition.⁷

WHAT IS THE PROPER DOSE OF ANTITOXINE?

That dose of antitoxine which will inhibit the extension of the pseudomembrane, subdue the fever, and check the progress of the disease in general. For a mild case of diphtheria from 2,500 to 5,000 units should be given. If there is no improvement noted in twelve hours and the exudate, temperature, and pulse remain the same then another dose of 2,500 to 5,000 units should be given. If there is a large exudate on the tonsils and pharynx and the cervical glands are enlarged, then it is safer to inject 5,000 to 10,000 units on the first day of illness. If no improvement is noted repeat this dose in twelve hours. The same dose should be repeated from day to day until all visible exudate has disappeared, the glandular swelling subsided, and the fever, if present, reduced to normal.

The condition and not the age of the child should be the guide as to the dosage. A toxæmia in a young infant is absolutely identical with the toxæmia of an older child.

To produce effects with belladonna we know that it must be pushed until its physiological effect is manifested. The same is true with antitoxine. To produce results give enough.

Idiosyncrasies.—I have never seen a case that showed ill effects from large doses of antitoxine; on the contrary. The blood serum—if anything acted as a nutrient and restored serum for the devitalized system.

Croup Cases.—When we are dealing with laryngeal stenosis due to diphtheria then the first injection of antitoxine should be at least 10,000 units. It is surprising to see how quickly the system responds in many cases. Exfoliation of membrane can be noted as early as twenty-four hours; in other cases it takes forty-eight hours or seventy-two hours. This exfoliation necessitates earlier extubation than formerly, and I have seen patients who, when extubated forty-eight hours after sufficient antitoxine was injected, could breathe without recurring stenosis.

I do not wish to infer that all cases can be extubated after forty-eight hours and remain cured, but I have seen cases that were extubated to relieve exfoliated pseudomembrane and the child got along without further tubing.

Nasal Cases.—The worst cases of diphtheria and the most fatal are frequently nasal cases. Excellent results have been seen by me at the Willard Parker Hospital when large doses of antitoxine were used. Septic and nasal cases require the same dosage as laryngeal cases.

WHAT CAN BE GAINED BY GIVING ENOUGH ANTITOXINE TO NEUTRALIZE THE TOXINE PRESENT IN THE SYSTEM?

First; we can limit the disease, and prevent the extension of the pseudomembrane into the posterior nares or downward into the larynx or bronchi; we can by this means prevent the most dreaded and most frequent fatal complication, namely, bronchopneumonia.

Second; by neutralizing the toxine we prevent degenerative complications, such as myocarditis and nephritis.

Third; we undoubtedly prevent postdiphtheritic paralysis, which has been recently emphasized by Comby, of Paris.

Fourth; when laryngeal stenosis exists the intubation period is shortened.

Immediate Effect of Antitoxine on the Temperature and Pulse.—In some cases there is a slight reaction, such as a rise in the temperature of one or two degrees, although many cases exhibit a decided fall in the temperature within twelve hours after an injection of 5,000 to 10,000 units. As a rule, the pulse rate is not affected. In some instances a very rapid pulse, such as 160, had dropped to 140 or less in twelve hours after an injection of antitoxine. In a septic case complicated by myocarditis, in which treatment was begun on the seventh day of the child's illness, a myocarditis was found. The pulse rate was 76. Twenty-four hours after an injection of 10,000 units the pulse rate was 82. Another dose of 10,000 units was injected forty-eight hours later. The pulse rate twelve hours later was 84.

A temperature of 103° dropped to 99° in forty-eight hours after 8,000 units had been administered. As a rule the temperature falls after the required dose of antitoxine has been administered.

Next in importance to giving the proper dose of antitoxine is the nutrition of the body.

FEEDING OF TONSILLAR AND PHARYNGEAL CASES.

Mouth Feeding.—As a tissue and blood builder no medication equals food. It is, therefore, imperative to support the general nutrition by proper feeding. Milk diluted with some cereal decoction, like oatmeal, barley, or rice will be better borne than pure milk alone. Sometimes it is necessary partially to peptonize to render it more absorbable. If the child is old enough the yolk of a raw egg can be added to the milk. Concentrated beef broth, chicken broth, clam broth, or oyster broth should be thought of. When feeding once in three hours, it is a good plan to give some of this concentrated broth, followed in three hours by a milk feeding, and so alternate. In this manner we give our patient milk once in six hours. Acid fruits, such as oranges, lemons, grapes, and cranberries, are very well borne. When acid fruits are ordered they should be given an hour before milk feeding. Older children can be given raw scraped steak, calf's foot jelly, and ice cream, which is nutritious and pleasant.

⁷ For a more complete description of rashes and their details I refer to my forthcoming book on *Diseases of Children*, in press of F. A. Davis & Co., Philadelphia.

FEEDING OF INTUBATION CASES.

Natural methods of feeding an infant with an ordinary feeding bottle, in an older child from a cup or spoon. Bread or crackers soaked in milk, toast in milk, zwieback in milk, the yolk of a raw egg beaten with powdered sugar, rice or corn-starch pudding, junket, custard, and jellies, are nutritious.

In rare cases in which the tube is frequently autoextubated and where no food is taken, rectal medication may be necessary to sustain life.

Rectal Feeding.—No more than two ounces should be injected at one time.

Milk, predigested.....	I ounce;
Starch water.....	I ounce;
Laudanum	I minim.

To be injected slowly through a colon tube, after both colon and rectum have been cleansed by a soapsuds enema.

If the small nutritive enema is well retained then we can repeat the injection once every four hours, and add the yolk of a raw egg.

Children will swallow milk and broth when fed in the dorsal position on the lap of the nurse. The Casselberry method is quite useful in most cases.

Gavage.—Forced feeding with the aid of a catheter *has never been used by me in private practice.* I have frequently seen bleeding produced by pushing the catheter through the nose, denuding membrane and opening up new areas of infection. The question as to whether pseudomembranous masses cannot be pushed directly into the stomach, causing a diphtheritic gastritis, is worth considering.

COMPLICATIONS.

Complications that arise during the case of diphtheria, such as pneumonia, myocarditis, nephritis, polyarthritis, or otitis, require the same treatment as they would if not associated with diphtheria.

The ordinary shortcomings that are most frequently met with consist of first, placing too much reliance on the specific nature of antitoxine regardless of other vital necessities. In addition to the required dose of antitoxine, vitality must be supported by food. The toxine of diphtheria causes distinct atony of the stomach and bowels, hence it is important to aid the emunctories by stimulating them. Hot saline colonic flushings at a temperature of at least 115° to 120° will cleanse the colon, stimulate diuresis, and when absorbed into the system will modify by dilution the toxine in the system. The heart should be carefully watched and supported by caffeine, sodium benzoate, musk, strychnine, and small tonic doses of quinine.

Restorative treatment should be remembered during convalescence.

65 EAST NINETIETH STREET.

THE TREATMENT OF DISEASE WITH
THE ROENTGEN RAYS.*

By W. P. GOFF, M. D.,

CLARKSBURG, W. VA.

I will not attempt a detailed description of the many diseases, in the treatment of which the Röntgen ray has been applied with gratifying results, but in a brief way will call attention to a few of the conditions in which I have found it of great value. Like many therapeutic agents, its value is not appreciated and not generally accepted by a large majority of the profession, but this unfavorable opinion is probably fast disappearing, and, moreover, the treatment itself is much more agreeable and attractive to the patient than other therapeutic agents that might be used in some cases with gratifying results.

CASE I.—I saw the patient in October, 1903, when she gave the following history: Married, age 50 years, general health had always been good. About one year previous to first seeing her, she noticed small red spots on fingers, which rapidly transformed into large blisters, remaining as such for about three days, then disappearing, which took about three days' time; then the hand remained normal for two days, when the same condition would reappear and take the same course as already mentioned. The blisters contained a cloudy fluid, and the patient stated she had received much relief during each attack by opening them. She had been treated by several physicians, but I was unable to get their general treatment. The condition became so bad on one finger that the latter was amputated—this before the blebs had ever appeared on the hand or wrist. Fig. 1 shows the condition as it was on the first

FIG. 1.—Case 1, before x ray treatment.

day patient called for treatment. I applied the Röntgen rays daily for a week, the exposures last-

* Read before the Harrison County Medical Society.

Personal.—Frank Parsons Norbury, A. M., M. D., editor of the *Medical Fortnightly* and medical superintendent of Maplewood Sanatorium, Jacksonville, Ill., has accepted the chair of nervous and mental diseases at Keokuk Medical College.

FIG. 2.—Case 1, after treatment.

ing from five to ten minutes, and after that twice and three times a week for the same length of time, until towards the end of December. At the end of the first week I had set up quite a dermatitis, which lasted for about a week, during which time there was disappearance and return of the blebs as already stated. At the end of the third week, the blebs entirely disappeared, and until this time there has been no indication of their return. I gave thirty exposures in all, but I believe that the good result obtained could have been reached much sooner had the patient

FIG. 4.—Case 2, after treatment.

lived where she could have taken treatment regularly, or at such times as I thought advisable. Unfortunately she lived in the country, and when desirous of giving two or three exposures consecutively, I would frequently be prevented from doing so by her inability to come to my office. Fig. 2 shows the hand as it is to-day, and there has not been the slightest indication of any return of the trouble.

CASE II.—A. N. L., aged 52 years, general health good, noticed about two years ago a slight abrasion on the cheek, but thought nothing of it

FIG. 3.—Case 2, before x ray treatment.

FIG. 5.—Case 3, before x ray treatment.

FIG. 6.—Case 3, after treatment.

at the time, until a crust formed, which upon becoming detached while bathing the face, left a small ulcerated spot, from which occasionally a few drops of blood flowed. This process of temporary scabbing over began without causing any pain or inconvenience, although there was a general increase in the ulcerated area. After six months the growth began to spread more rapidly, and with the spread of the ulceration there was itching and some pain. No particular treatment was adopted until the patient presented himself September 1, 1903. After examination, I suggested the Röntgen ray treatment, and made a microscopical examination from a section taken from the affected spot, so that we might determine accurately the cause of the trouble. The result of this examination demonstrated that the diagnosis of epithelioma was correct. I continued the exposures until January 1, 1904, before feeling satisfied that the patient could discontinue them permanently. Fig. 3 shows the condition of the patient when treatment was begun, and Fig. 4 as it is to-day. In this case, as well as in the one previously mentioned, I was interrupted in giving the exposures with any degree of regularity, sometimes three or four weeks intervening without treatment. At the present time there is no indication of any return of the diseased condition, and no exposures have been given for several months.

CASE III.—A. B. H., aged 50 years, noticed about December 1, 1903, tenderness and redness over the sternum, which gradually increased in extent until small ulcerated spots appeared, from which at times would flow a few drops of watery fluid, and later some pus. The soreness increased to such an extent that the patient was compelled to give up his business. I first saw him March 11, 1904, and was told that he had been using different salves for the past four months without any beneficial result. The history was very incomplete, being entirely negative, and therefore I was unable to make a satisfactory diagnosis. His general health was much impaired; he had become very nervous and depressed over his condition. As shown in Fig. 5, taken the day that the treatment was begun, a nodular condition will be noticed which, according to the statement of the patient,

FIG. 7.—Case 4, when x ray treatment was begun.

began about two months previously. After making an examination and believing that the infected area in all probability contained pus, I

FIG. 8.—Case 4, at the end of treatment.

suggested that it be thoroughly drained, which, however, the patient absolutely refused. The exposures in this case lasted from eight to twelve minutes, having been given four times a week for three weeks, and about twice a week thereafter until towards the end of June, 1904. No improvement was noticed until after the first month. The soreness and inflamed condition gradually disappeared, and to-day the patient experiences no trouble whatever. His general health has much improved, and the nodular condition has entirely disappeared, as shown in Fig. 6.

CASE IV.—R. B., aged 55 years, presented himself for examination and treatment August 5, 1904, and gave the following history: 28 years previously he was struck under the eye with a pitchfork, making two punctures of the skin, one quite deep, which bled profusely for a few minutes, but no special treatment was employed. At times it gave evidence of healing completely over, but did not do so entirely, always breaking down before the process of healing was completed. Frequently the area of healthy skin surrounding the sore would become somewhat inflamed, and he was conscious all the time of some soreness. The process of temporary scabbing over had continued for the past twenty-eight years, but recently—within the previous six months—the infected area had seemed to increase somewhat in size. The patient gave a negative history and presented himself for treatment on the date given. The condition when treatment was begun is shown in Fig. 7, which was taken the day treatment was begun. In this, as in the others, each exposure lasted from five to eight minutes, seventeen exposures being made in all. I gave an exposure of five minutes daily for five days, then every other day, until ten exposures had been given, and then as the condition of the parts would allow. At the end of twelve exposures I had set up quite a dermatitis, and then discontinued treatment for a week. The patient is now well, as is shown in Fig. 8. It is of course too early to state what the condition will be in a year from now, but I have no reason to believe that there will be any return of the trouble.

Mortality of Michigan During May, 1905.—The total number of deaths reported to the Department of State for the month of May was 2,700, a decrease of 322 from April. The death rate was 12.5 per 1,000 population, as compared with 14.4 for the preceding month. By ages there were 456 deaths of infants under one year, 140 deaths of children aged one to four years, and 837 deaths of elderly persons aged 65 years and over. Important causes of death were as follows: Tuberculosis of the lungs, 204; other forms of tuberculosis, 28; typhoid fever, 22; diphtheria and croup, 28; scarlet fever, 5; measles, 20; whooping cough, 16; pneumonia, 171; meningitis, 43; cancer, 147; accidents and violence, 181. There were also 18 deaths from smallpox, one in the city of Detroit, one in the city of Big Rapids, Mecosta county, one in Walker township, Kent county, and 15 in the city of Grand Rapids.

ANÆSTHESIA IN THROAT SURGERY.

By HENRY WALLACE, M. D.,

GLEN RIDGE, N. J.,

ASSISTANT PHYSICIAN, MOUNTAINSIDE HOSPITAL, MONTCLAIR;
RECENTLY ASSISTANT LARYNGOLOGIST, ST. JOHN'S HOSPITAL AND POLHEMUS CLINIC, BROOKLYN, ETC.

The administration of an anæsthetic is a post of responsibility, and too frequently relegated to the inexperienced. In the majority of cases it is next in importance to the operation, and the fact that in not a few cases we fear the results of the anæsthetic more than of the operation places its administration in the first rank of responsibility.

There is nothing more trying to the surgeon than to be continually obliged to keep his eye on the anæsthetizer and be unable to concentrate his entire attention upon his own work. It is for this reason that the writer has always felt that the art of surgical anæsthesia is worthy of the attention of a specialist and believes that there is a large field for those who will devote their time and attention to this subject.

The average medical graduate is woefully ignorant of the subject and the fortunate minority who receive hospital appointments are almost the only ones who get practical training in this important branch.

In throat surgery, the choice of anæsthetic, the degree of narcosis, and the position of the patient are the special points worthy of our attention and these will depend very largely on the individual operator. There are some who ignore anæsthesia, local or general, in these cases, and there are others who prefer the swifter anæsthetics, such as nitrous oxide or ethyl chloride. The great majority, however, operate under general anæsthesia and consider it cruel to do otherwise. Such being the case, the study of some points of importance in the production of narcosis in these cases may not be amiss.

As to operating without anæsthesia, let me quote a statement of Ingals's, made in a paper of recent date, detailing the technics of his cold wire snare operation for tonsillar hypertrophy. He says: "Furthermore, we should not forget that the fright and pain to the little one caused by amygdalectomy is often as great as that an adult would suffer from amputation of the arm." Some of us may think that this is putting it rather strongly, but there is no doubt in the writer's mind that the combined operations of amygdalectomy and adenoidectomy at one sitting produce a degree of shock which no child should be permitted to endure. Ingals's statement, however, shows the feeling of one well known spe-

cialist on the subject and without question many can be found to agree with him.

Gradle, of Chicago, removes the tonsils without general anæsthesia. He says, in his work on *Diseases of the Nose, Pharynx, and Ear*, that "Tonsil operations require anæsthesia only when active resistance on the part of the patient is to be expected. The pain is considerably reduced, but not entirely avoided, by free brushing with a twenty per cent. solution of cocaine." Gradle also performs adenoidectomy without anæsthesia. He states that "Narcosis makes the operation more formidable and necessitates more assistance. It does not in any way permit a more thorough operation, as most of the relapses which the writer has seen had been operated upon previously by others, or by himself under anæsthesia. The pain in well arranged operations is not sufficient to necessitate the superfluous risk of an anæsthetic." However, he later states that "Narcosis is also preferable when the faucial tonsils are to be exercised at the same sitting, as this triple operation is usually too severe a tax on a child's tolerance." Although many operate satisfactorily under nitrous oxide or chloride of ethyl, the writer believes that the *average* operator requires a longer period of narcosis and a more complete relaxation than is ordinarily produced by them to enable him to do a thorough tonsil and adenoid operation.

His preference is decidedly for ether in all cases, preceded, where possible, by nitrous oxide. The results have been uniformly good, and as he does not class himself among the very rapid operators this sequence has proved most satisfactory.

Without question, both patient and operator are to be congratulated on the power of nitrous oxide to bridge over the stage of irritation and excitement produced by ether, and thus almost eliminate the element of fear in our young patients.

Chloroform.—In these cases, the first and last statement in the discussion of this anæsthetic should be one of condemnation; the object of such condemnation being to sound a note of warning to members of the profession, and especially to those in general practice who operate in these cases and who may not be aware of the risks they run in selecting chloroform as the anæsthetic.

Under ordinary circumstances chloroform is considered about five times as dangerous as ether. Reference has been made to the effect of fear as a contributing danger, and in this connection I quote from Patton, of Chicago, in his work on *Anæsthesia and Anæsthetics*. He states: "There are various factors which constitute a source of danger during chloroform inhalation besides the toxic action of the drug itself. Psychological causes may contribute toward danger or death early in the ad-

ministration. Cases have been reported by various observers of death apparently due to fright alone before the administration had begun. It is a fact, however, that the cases of fright syncope are practically limited to cases where chloroform has been employed, and we must therefore regard psychological influences as merely a more potent contributory cause under chloroform than under other anæsthetics."

It is interesting to read what Lennox Browne has to say on the subject of anæsthesia in throat surgery. Generally speaking, the Europeans have been much more partial to the use of chloroform than we, yet this writer, as he himself states, is "an energetic opponent of the administration of chloroform under such circumstances." His preference is very great in favor of gas "when dealing with operative measures which to the dexterous occupy but a few seconds, and have little or no claim to be dignified as aught but manifestations of minor surgery." This statement may be true from his standpoint, but there are a goodly number of special operators, and competent ones, too, who do not look so lightly upon these operations and for whom gas would not be the ideal anæsthetic by any means.

In his objections to chloroform this writer seems to lay most stress on its dangers from mechanical causes. In addition to the danger of the fact that chloroform abolishes the cough reflex so as to favor the entrance of blood into the larynx, he emphasizes the fact that these patients are already suffering from air starvation and require a smaller dose of the anæsthetic, being, he says, "as it were, in their ordinary condition already advanced a stage toward asphyxia." Hence are explained those not infrequent cases in which chloroform has been used in nasopharyngeal surgery and the patient has died before the operation had actually been begun.

It is true that the advantages of gas are that the cough reflex is not abolished, that the narcosis is not so profound and may be discontinued almost as soon as the mask is withdrawn, as is not the case with chloroform or ether, and, finally, the readiness of the patient's recovery without after effects. So far, so good, but this writer makes no reference to the condition of lymphatism which these cases represent and the dangers of chloroform anæsthesia in such. One might properly infer, as he speaks of this condition only to define it according to Loewenberg and gives the names of well known men who do not consider that this diathetic state constitutes an ætiological factor in the production of adenoid growths, that he regarded the dangers of chloroform as mechanical rather than constitutional. However, there is not much doubt that the constitutional peculiarity or dyscrasia known as lymphatism, or the *status lymphaticus*, bears chloroform badly

and that there are weighty reasons, other than mechanical, why chloroform should be avoided. Constitutional reasons have never been urged against ether in this condition, or in fact mechanical ones, although we all know that in cases of marked crowding of the passages, anæsthesia proceeds more rapidly and smoothly after the first strokes of the operative attack. The mechanical objection against chloroform is based on the fact that air should form a large portion of the mixture, and herein lies the danger when it is not properly administered.

In the August 27, 1904, number of the *New York Medical Journal and Philadelphia Medical Journal* will be found an account of a chloroform death after an adenoid and tonsil operation. This case was evidently a good example of the lymphatic temperament in which there was tonsillar and adenoid hypertrophy. The article states that, after a hurried circumcision and a rapid throat operation, the patient exhibited a sudden failure of pulse and immediate cyanosis of the face, and that, in spite of every known and available means of resuscitation, the patient died.

The paper goes into detail regarding the gross autopsy findings, which proved conclusively that it was a case of lymphatism, and concludes with a statement, made by a jury of physicians at the coroner's inquest, which exonerated the physicians and the hospital on the ground that the death was due to cardiac paralysis following chloroform anæsthesia occurring in a subject having a disease not determinable before death, and because every possible precaution was taken in the case. Here the danger was evidently not due to mechanical causes, for the danger signs did not appear until after the completion of a circumcision, an amygdectomy, and an adenoidectomy. Had it been due to mechanical reasons, pure and simple, would it not be natural to infer that the danger signs would have manifested themselves earlier in the operation?

The *American Year Book of Medicine and Surgery* refers to Chaldecott's article in the *Lancet*, of September 13, 1903, in which he condemns the use of chloroform in these cases and refers to fifty instances of death occurring in these otherwise simple operations, and in which he further makes statements as follows in regard to chloroform, ether, and the other anæsthetics: "Even in the hands of an experienced anæsthetist, chloroform in these cases is extremely dangerous. For infants less than twelve months old ether should be employed on an open mask. Children from one to four years of age do not take nitrous oxide well, especially if there is any obstruction of the respiratory tract. Ether in these cases is usually taken without trouble. From four to twelve years of age nitrous oxide is gen-

erally satisfactory. This agent is also usually satisfactory in adolescents and adults. Gas and ether are to be preferred to gas and oxygen." The author closes with repeated advice against the use of chloroform in nose and throat work.

In the same volume are given the results of McCardie's experience with ethyl chloride, published in the *Lancet* for April 4, 1903. This writer gave ethyl chloride in 620 cases, a large proportion of which were throat or tooth cases. Its advantages are much the same as those of nitrous oxide, and he states that the rapid production of anæsthesia is sometimes startling, occurring in one instance after six full breaths.

If anæsthesia is not induced in less than a minute, or a minute and a quarter, it is because air is being admitted too freely to the inhaler or because insufficient ethyl chloride has been given. In operations on the throat and nose, McCardie prefers the patient to assume the recumbent posture, the head being somewhat lower than the body. In none of the 620 cases mentioned had he noticed any syncope, either cardiac or respiratory, the only difficulty arising from obstruction of respiration, the result of hæmorrhage or the falling back of the tongue. When full anæsthesia is employed the muscles are almost invariably flaccid, although rigidity has been complained of by a number of writers. The only contraindication to the administration of ethyl chloride is marked narrowing about the larynx, when McCardie considers chloroform a better anæsthetic, as it is less stimulating. In most of his cases he used a Hewitt inhaler.

As to the degree of anæsthesia, the writer's preference is decidedly in favor of narcosis to the extent of palatal relaxation. Unless there is a marked relaxation of the soft palate, the use of instruments in the postnasal space is difficult, uncertain, and dangerous. He finds that it is advisable to get the patient well under the anæsthetic and complete the operation as far as possible before the palatal reflex returns, attend to the hæmorrhage, and give more ether, if necessary, to make removal thorough.

As to the position of the patient, the writer, after a fair and impartial trial of all the usual positions but the lateroprone, uses almost universally the dorsal position with moderately lowered head. As to the upright position, we must agree that it takes some special training to anæsthetize properly and further the operator's efforts. The upright position is preferred by a good many well known operators. Hooper, who was probably one of the first to realize the importance of adenoid growths in this country, and the late Morell Mackenzie are among them. French, of Brooklyn, invariably prefers this position and has devised an excellent chair for

facilitating the handling of the patient. The only advantage that I can see in the upright position is that the operator is credited with being more familiar with the landmarks, having been accustomed to perform the majority of his manipulations with the patient sitting erect in his office chair. However, this seems to be but a point of minor importance, for very little practice would render him as familiar with the faucial and postnasal landmarks with the patient in the dorsal or other position. It is stated by those who prefer it that there is less danger of ear complications after operation, by favoring the drainage of blood from the fossæ of Rosenmüller. It is averred on the other hand that there is more danger of blood entering the air passages by gravity.

As far as the writer has noticed, after a considerable experience both as anæsthetist and operator where the upright position has been employed, there has been little or no trouble with blood entering the larynx where the correct technics was employed. On general principles it seems that the patient should conform as nearly as possible to the usual and safest anæsthesia position, especially if the operator cannot count on an anæsthetist trained to work with the patient in the upright position and where he will have no other assistant. To reduce the number of assistants and to operate with the greatest convenience, especially in house to house work, the writer has devised a portable head rest attachable to any table.

Dr. Wallace's portable head rest.

This rest has the advantage of steadying the patient's head as it depends at any desired angle over the end of the table. In this position it is difficult for blood to enter the larynx. In using the rest, the patient is anæsthetized before placing the head on it. Too great extension of the head is inadvisable and should be avoided. Even in this position blood will enter the digestive tract, and, as unfortunate results have been attributed to this occurrence, some operators make a practice of washing out the stomach before the patient leaves the table. Vomiting after these operations is very likely to occur, owing to the absence of profound narcosis and the presence of the swallowed blood. Generally speaking, it is not to be considered undesirable that vomiting should occur.

To favor the passage from the intestinal tract of such blood as is not ejected in this way, it is the custom of many of us to give the patient a dose of calomel, or a saline, or both, as soon as the stomach will retain the medication.

SUMMARY.

It seems, then, from the writer's standpoint at least, that for the operator of average skill, the gas ether sequence, with narcosis pushed well to palatal relaxation, the patient being in the dorsal position with moderately lowered head, secures the best results as regards least danger to the patient and the greatest facility of operative technics.

Annual Meeting of the American Medical Society for the Study of Inebriety and Alcohol.—

The thirty-fourth annual meeting of this society will be held in the hall of the Atkinson School Building, Portland, Ore., July 12 and 13, 1905, beginning at 9 a. m. The president's address, by Professor W. S. Hall, of the Northwestern University of Chicago, Ill., will be a review of the progress of the study of the action of alcohol during the year. The Committee on the Influence of Alcohol in Literature and History will present a report by its president, Dr. John Madden. The Committee on Heredity as a Cause in the Disease of Drug and Spirit Taking will report, and the Committee on Patent Medicines will also submit a statement of their work. Papers will be read by Dr. MacNicholl, Dr. Steward, and others. The second session, Thursday, July 13th, at 9 a. m., will be a memorial service to the memory of the late Dr. N. S. Davis, and a continuation of a similar meeting before the American Medical Association. Addresses are expected from Dr. Hall, Dr. Webster, Dr. Crothers, Dr. Kellogg, Dr. Hollister, and remarks by ex-presidents Musser, Billings, Mathews, and President McMurty, of the American Medical Association. The public are cordially invited to be present. T. D. Crothers, M. D., secretary.

Lectures and Addresses.

THE MODERN DOCTOR.

By A. JACOBI, M. D., LL. D.,

NEW YORK.

(Concluded from page 1201.)

The more you know the better will you be in a position to judge of the utility of new teachings, theories, and methods. Let me give you an instance of what occupies many medical minds just at present. Infectious diseases, such as rheumatism, scarlatina, etc., are believed to enter the organism through the throat. The teaching is that they pass in through the tonsils. Now, it is true that the tonsils consist of lymphoid tissue which is apt to absorb whatever comes in contact with it, particularly when the surface is sore, maybe in consequence of a burn, a hot drink, or a cold. Even tuberculosis has been believed to enter through the tonsils, and a modern author has preached a crusade against the tonsils. They must be removed totally if mankind is to be freed from its arch enemy. Unfortunately, however, this author added that there were very few men living who could remove the tonsils according to his effective method. In the same way the tonsils are charged with admitting other infectious diseases. But as early as 1860 I proved that diphtheria, for instance, when it affected the tonsils alone was mild, while the danger was great when the neighboring surfaces, particularly those of the nose, were affected, and twenty years later I was able to publish the anatomical reasons for that difference. So I have no doubt that the tonsil theory will be restricted. Indeed, in comparison with the dozen lymphoid follicles of which the tonsils are composed, there are thousands in the proximity. It is through the latter rather than through the tonsils that the invasion of infecting microbes and toxines takes place.

Why do I say all this? Because I wish you not only to be willing recipients of great men's gifts, but to learn to see with *your* eyes, to hear with *your* ears, and use *your* judgment. Believe Epicharmus when he said 2,000 years ago: "Sobriety and constant doubt, these are the marrow and bone of the mind."

It is not necessary to live in big medical centres to make good and epoch making observations or even to write immortal works. Beaumont was a military surgeon in one of our outposts when he gathered the materials for his *Experiments and Observations on the Gastric Juice and the Physiology of Digestion* (Plattsburg, 1833). Drake was a practitioner and teacher in a small town

when he published his *Diseases of the Mississippi Valley*; McDowell was a country practitioner in Kentucky; Marion Sims in Alabama.

You gentlemen have been born and bred in a democratic country. Thus it should be easy for you to have respect for the individual patient, male or female. I know that what I have seen in European clinics could never happen in our country. In Europe they expose nude women for half hours at a time, shivering and almost annihilated with shame and terror, to the gaze of students and nurses. Our students would scorn and hiss the teacher who would thus blunder or sin. That is why you American men will find it easy to imagine yourself in a patient's place. Where you cannot save, you can relieve or comfort. Now, a learned and sagacious friend in the Far East has repeatedly expressed his opinion that truth should be told in every case no matter what the result. I decline, have ever declined, to follow that ruling. I never told a patient he must die of his illness, and I hope I never shall do so. Tell a patient he must die of his cancer, and you will shorten his life and make the brief remnant of it miserable beyond description. Tell the truth to one of his reliable and discreet friends.

Truth is a remedy. Both have their indications as to individuals and timeliness. The same remedy, given at different times and for different conditions and to different persons, may have different effects. Never forget that the good of your patient is your first and only object. To tell the whole truth will sometimes kill, in other cases it will benefit, provided it is given in proper doses. For instance, a patient will come with a cough and short breath and the history of frequent colds; perhaps even of occasional bleeding. He has the physical symptoms of pulmonary tuberculosis and you find tubercle bacilli in his sputum. Will you tell him that he is tuberculous or will you conceal the fact? When you tell him he is tuberculous he will ask the momentous question: I never thought I was consumptive; what will you do about it? I think the very solution of the difficulty, if there is any, is this: You will tell him that he is tuberculous, but not consumptive, that he is not going to die, that he may become consumptive if he should get worse; that many, indeed most people like him have a good opportunity to get well, that it is a common experience to find people die of all sorts of diseases at sixty or eighty years of age, in whose lungs there are tubercles healed; that, indeed, there are comparatively few persons who have had no tuberculosis some time in their lives; that he can save himself and protect his family with a moderate amount

of care and foresight. You may do that and be truthful. You tell him truthfully that he has tuberculosis and that it is his duty to get well. What you will not do is what I experience several times a week. A poor patient tells you his doctor has told him he has consumption, and unless he goes to Colorado at once he will die. Imagine a poor person, very often with a wife and children, with no money to pay even his railroad fare, much less to live upon, told in just so many words that he cannot be helped. There are much ignorance, thoughtlessness, and cruelty in the intercourse of men, but I know of no act of brutality that equals this treatment of poverty and malady stricken persons on the part of members of our own profession. There is no reason to indulge in it in your relations to the sick. If you have the cruelty of your convictions, try it on the rich who are independent of you, but neither on the poor in private life nor on hospital patients.

Never, my young friends, give up watching a case as long as you are in charge. Most cases of disease have a tendency to get well; that does not mean, however, that the sufferers should be left to themselves; for the measure of strength saved from an illness determines the duration of convalescence, the restoration of the tissues, and the future power of resistance. Many may recover unless they are neglected; if they do not so recover, their blood is on your heads. Some will die no matter what you do or try; even then euthanasia is welcome if you cannot procure more; it is better than the anguish and the suffering of many that are moribund. In many such conditions the question has been raised whether or not it might be permitted to shorten the life of a hopeless martyr who is in torture which *must* end in death. I was present when a minister of the gospel in my city rebuked us doctors roundly for not finishing the misery by a friendly poison. When I heard it, I remembered the little sentence in the Latin primer of my early childhood: *Medæ projeciebant moribundos canibus*; the Medes threw the dying to the dogs. When we doctors become Medes, we shall obey the ruling of that clergyman. Meanwhile we have sworn with Hippocrates: "I will give no deadly medicine to any one if asked, or suggest any such counsel."

In order to fulfill the indications required by the sick, the convalescent, or the dying, make yourself acquainted with the rules of nursing and dieting, and with the nature and effect of remedies both external and internal. When I was a young student, the medicine of Germany was just waking up from a forty years' slumber caused by the unintelligence of what was called *nature phil-*

osophy. At that time the Viennese learned pathological anatomy from the French. One of the greatest teachers of that branch was Rokitansky. For him all there was in medicine was the study of the dead body. For Skoda, however, all there was in medicine was diagnosis, mostly through percussion and auscultation. For the patient, all there was to do was to go to the hospital, to be diagnosticated by Skoda, and to be opened by Rokitansky. Medical science and the patient met only twice, once on the hard hospital bed, next on the autopsy table. The doctor had done his full duty when the diagnosis and the result of the post mortem examination agreed. Of therapeutics there was none. The time of the big medicine bottles with the nauseating draughts had gone by, thanks to Hahnemann; whatever was presented by Hahnemann, however, could not meet with the approval of sophisticated savants. So there were no drugs, no treatment. While formerly both medication and bloodletting had been overdone, now everything was discarded. Dietl, of Vienna, and Hammernjk, of Prague, founded that nihilism of the Vienna school that under the flag of so called pure science had resulted in driving the patients into the camps of sectarians or quacks, who after all do hold out some promise to the despairing.

All that has changed; modern medicine has learned its responsibility to the individual patient and to the community. We have entered upon a new era, that of therapy; both the individual and the community are recognized as claimants upon our bounty.

Gentlemen, you are not alone in the world, nor in the profession. You could not live a hermit in the midst of millions, away from the village, county, State, nation, and the universe. A hundred ties bind you to benefit and be benefited by the rest. So you are bound up with the profession from the first day you enter it. I advise you to join one or more societies at once, at all events your county society, or any other that commends itself for its scientific work or for its affiliation with the American Medical Association. The complaint we often hear that there are too many medical societies may be justified as far as large cities are concerned, but there should be enough of them all over the country to give an opportunity to every practitioner to join at least one. The benefit to all its members is mutual. As there is a political, so there is a professional citizenship, meant to improve the individual, increase his knowledge, compare experience, adjust mistakes, and learn modesty. We were not made to be alone. Capsulation kills the efficacy of tri-

china, bacilli, and men equally; and the interests of a profession or a political commonwealth are not safe unless in the application of a universal democratic spirit. Nor can great results be obtained except by the altruistic cooperation of many. Legislators were aware of that more thoroughly a century ago than at present. At that time they were always willing and anxious to endow the medical profession with such legal rights and privileges as would enable it to look after the interests of public health and sound legislation. Even the authorization to practise was left to their judgment. Nor has the profession ever to my knowledge misused the confidence placed in it. The Sanitary Commission of the civil war which has become a model for the world's imitation and the spiritual mother of the Red Cross was controlled by the spirit of such eminent doctors as Cornelius R. Agnew and Ernst Krackowizer. The fight against epidemic diseases, which, as Virchow expresses it, should teach a statesman that when they exist they are a preventable or curable disorder in the social and political organism, has always been taken up by medical men. Unfortunately, however, it is too often true what Anarcharsis said of Athens, that the wise men do the talking and the others the acting. A few weeks ago, Gorgas and Reed and Panama formed no exceptions. A number of years ago we spent a million a day on a war of our making while a mere quarter of a million was refused that was to be spent on an instruction camp and life saving station. With what we spend in half a year to keep the survivors of a foreign population in subjection, we could eradicate tuberculosis from the United States within a generation. The battles against disease, prejudice, shortsightedness, and incompetence are always fought by the medical profession, sometimes in single combat, more effectually, however, by consolidation and cooperation. To this profession you have dedicated yourselves. Be sure, my friends, that its practice be not a trade for you, but a vocation and a sacred calling.

Many of you will enter the practice of medicine within a reasonable time. When your medical neighbor has patients, while you are still waiting, never grudge him his own, and—wait. When the first one has turned up, never feel that you own him. When your neighbor is well spoken of, do not believe that your reputation suffers when he is eulogized, and watch your shoulder lest it shrug. It is better that patients should seek you than that you run after them. Do all you can and all the teaching of your medical friends and of such books as you have rea-

son to believe in. Do not despise after your graduation a good text book. I consult them to-day, aye, even my own, for on a page or two some of them may contain the ripe experience of a generation; indeed, not every text book is compounded by a young man at the beginning of what he means to become a brilliant career. In the beginning of your practice—and later on for that matter, if time permits—be sure to read up in reference to every case under your care, and take exact histories. Never believe you know all about any case, or enough—for I assure you you don't. At least I don't, though I have studied medicine nearly sixty years. When a patient leaves you for some other doctor it depends on your temperament, or vanity, or needs whether you feel chagrined; but do not blame the doctor who is called in your place. On the other hand, when another doctor robs you of your patient by hook or by crook—they say such things do happen—be sorry for that doctor, and for the profession he should not belong to, and be glad you are not the other man, but a gentleman. Remember that a gentleman finds it easy to compete honestly; when you are not treated that way, it worries you—but *you* are the gentleman, and people will eventually find you out. Not to take honest competition on the part of others kindly shows disregard for the rights of others, either doctors or patients, and bad citizenship, and exhibits jealousy, avidity, and senility of the young or the old heart.

Unfortunately we are not all angels. Indeed there was a time, not very far distant, when the facility of obtaining a diploma and the license to practise so filled the profession with undesirable men and women as to crowd the ideal as to what a physician should be to the wall. It is only with the growing difficulty of matriculation and increasing severity of examinations, particularly also the establishment of State license boards, that the number of underweight doctors has become smaller. Their large number and consecutive competition rendered, as it does in any trade or vocation, the obtaining of a livelihood more difficult, and subjected the morals of the profession to a severe strain. Moreover, the commercialism which is the signature of our period has invaded industries, arts, science, and the professions, but has not proved so detrimental as it has in Europe, where poverty is greater and the innate pride of our democratic citizens is absent. The moral requirements of the profession found their expression in the code of ethics of the American Medical Association, first enunciated by an Englishman, Percival, in 1807. It has cer-

tainly done much good; it is true it cannot make a gentleman out of an evil disposed person; no law can. It simply codified the rules a gentleman will obey without being told; but the inexperienced may be guided by its teachings. When finally, in 1882, we decided in the State of New York to modify and later on to abolish the code as a law book, as none was required to guide our methods of intercourse, the observance of the rules valid amongst gentlemen became even stricter in the profession in the State of New York than ever before. The result was, however, that our affiliation with the American Medical Association was interrupted. But such has been the gradual change of public opinion that the American Medical Association saw its way two years ago to abolish the code as a law book enforcing obedience, and to recommend for general acceptance in place of a criminal code a series of principles of ethics, not compulsory but suggestive, as a guide. This wise action has enabled the two warring factions in New York State to make active preparations for a lasting consolidation which is in the interest of both and, as we hope, also of the American Medical Association. The best men of the profession are actively engaged in overcoming the legal difficulties we met with in our way, and I know whereof I speak when I say that the old and tried men of the Medical Society of the State of New York, the very men who abolished the code as a law book with punishments attached, are pledged to accept the new principles of ethics as agreeable to them and a guide to the colleagues.

Now, gentlemen, there are two indispensable factors that render practical success possible. Do my young friends want to hear what they are?

Firstly, be sure to accumulate all the science and art within reach.

Secondly, acquire the confidence of your patient.

The first recommendation is the main thing. Acute infections, epidemic diseases with a limited or unlimited course, injuries, operative cases, the vast number of the disorders of childhood, indeed the greatest number of ailments with disturbances of the blood or of organs, require nothing but a clear insight into the nature of the disorders and the knowledge of the action of the remedies, besides energy, consistency, and the knowledge of what is either possible or impossible. No confidence of any patient will do him or you good. But, in a large number of nervous disorders, or of chronic diseases, the confidence of your patients, if you can obtain and retain it, is invaluable. When they know that you have

worked for knowledge and possess it, and that besides you place it in their service and are interested in them, their confidence will be a powerful asset in behalf of both parties concerned.

Constant study, my friends, should be a requisite. Whoever cannot or will not learn from every case he meets, will not improve. A hundred cases not studied are like the first. Experience is not gained by committing the same mistakes a hundred times; and an old man, who never had a young heart and a searching eye, was never a physician that deserved any confidence. It is true that confidence may be misplaced. There are men in the profession as well as outside of it who play the confidence game. A long while ago there lived in New York two doctors with whom I was intimately acquainted. One of them called on the other long after midnight—it was before the telephone era—for a consultation, and the following conversation took place: "I am glad to find you up, come along, but what are you doing at this time of the night?" "I am studying." "You are very queer. One quarter of *savoir*, and three quarters of *savoir faire*, that makes the successful practitioner." "Yes, that may be true, but where do you come in? For you have the three quarters of *savoir faire*, but not the one quarter of *savoir*." Perhaps you can imagine that diplomatic relations between the two men became strained and there was no other consultation after this.

Be honest in all things! Work! And while you are studying and applying your drugs, do not forget the principal remedies offered, not as they say, by nature—she offers poison and salvation with equal generosity—but by common sense. Exercise and rest, open windows, hygiene in general, diet in particular, hot and cold water are together a panacea when judiciously ordered. Frequently you may do without the apothecary. Then, however, your patient may turn upon you. "Is that all? Exercise, open windows, starving, cold water, no tobacco, no coffee, no high ball, and no prescription? Doctor, I know that much myself. I see I must go somewhere else. Now, doctor, really, is there any bill?" He does not appreciate that you have given him the quintessence of two thousand years' worth of medicine, goes to your neighbor, who gives him no quintessences, no two thousands years' worth of study, but a prescription and gets his ungrudged fee. Never mind, however, that very patient will some day return to you, will try to run down your neighbor, your so called colleague, and you—well you will stop him from so doing.

For you will not forget that since the man

does not know how to discriminate between doctors, you have to take the part of the profession in the person of your rival. The dignity of the profession should be upheld by and in every member. Do not speak ill of a professional brother, or half brother, or cousin, for the layman will take your sneer as a slur on the profession. Now, when you are asked for your opinion of a medical man, who is above the average in knowledge and virtue, or who is your peer, do not spare your praise; when of a doubtful or no longer doubtful person, tell your inquirer that you are not the judge of other doctors. Mind, whoever of you says, or is believed to say, anything derogatory to the profession, which is a calling, and not a trade, acts foolishly. While not benefiting his worldly interests, he is injuring himself, the medical world, and the public that should in its own interest be educated into respect and appreciation. And never forget that praise of the other man does not detract from your worth.

One more lesson which you may take or not. Those of you who labor in the most beneficent, but least paid part of professional work, I mean that of the general practitioner, must never get tired. A doctor has no right to be tired, he must not get sick unless he wants to be sneered at, most of all, he must not permit himself to die; a poor doctor who could not save himself, though he expected to save others! You should be prepared to enjoy all the miseries of life, many of which you cannot escape. There are, indeed, good reasons for doctors being serious and perhaps tired looking, for they have shared thousands of sleepless nights with their patients without finding rest the next day. But you are well off after all. Imagine you had been the doctor of Hephæstion, the friend of the great Alexander. When he died, the king was sad and rather displeased. So he crucified the doctor and burned the temples of Æsculapius. Imagine how you would feel if you were killed every time you lost a patient and medical schools were burned as a punishment. We are more modern, however. The only thing that is crucified is your good name, in addition perhaps to a malpractice suit. I have lived through both and I still hear a woman's shriek in a public thoroughfare fifty years ago: "There goes the murderer of my child." I tell you life is a serious thing, and you have to face it in the best way you can. Imagine you had been a practitioner in Venice under the rule of the God fearing Godfrey of Bouillon, only seven hundred years ago. If you had been a Christian doctor you would have had to pay for every slave that died under your care; if a

Hebrew you would have been hanged with a urinal in your hand. It should be your joy forever you did not live in the good old times of the Crusaders. What would you say to being a great discoverer and benefactor like Harvey or Gall, two of the great names in medicine. When and because they discovered and taught new lessons, they were persecuted and lost their practices. We are better off nowadays. But, still, listen to what I read in Ughetti's book—I believe he spoke of you and me: "When a doctor runs away from an epidemic he is a coward; when he stays and fights it, he is forgotten; when it kills him, his family will starve." I have seen all that and it looks gloomy, does it not? But you do not look frightened at all. And such is the fascinating sacredness of the calling you are entering upon, my young colleagues and fellow students, that if you asked an old man who had been through hard lifelong work and heart rending scenes, through successes, maybe, and endless failures and disappointments, if you asked him what he craved to be if he began life again, he would, I think, reply: "Just a modern doctor."

Therapeutical Notes.

Antidiarrhoea Tablets contain 0.25 gramme albumin tannate in each tablet, made agreeable to taste by the addition of sweetened chocolate.

Blutan is a carbonated solution of peptonized acid-albumin-iron-manganese, free from alcohol, and containing 0.6 per cent. iron and 0.1 per cent. manganese. The preparation is also put up with bromine and iodine, as in

Bromo-blutan, which contains 0.1 per cent. of bromine in organic combination, and

Iodo-blutan, containing 0.1 per cent. of iodine in organic combination and said to be a better tasting preparation than the ordinary compounds of iodine.

Catalase is the name applied to a special ferment in the animal and vegetable tissues which has the power of decomposing hydrogen dioxide. In animals it is found most plentifully in the liver, and the substance obtained from this organ, a brownish powder, has been called for obvious reasons hepatocatalase. This powder acts energetically on hydrogen dioxide water, one part decomposing 3,000 to 4,000 parts.

Cresylone is a non-toxic antiseptic solution containing 50 per cent. of cresylic acid. It is miscible with water in all proportions.

Emulgen is an emulsifying agent of recent introduction which is said to form good emulsions with oil in the proportion of one part of emulgen to five parts of oil. The substance is said to consist of tragacanth, 10 parts; acacia, 5 parts, gluten, 5 parts; glycerin, 20 parts; alcohol, 10 parts; water, 50 parts.

VARIOLA VACCINE.

We believe it is universally conceded by persons of experience in the matter that the so called variolation of the cow is an undertaking of great difficulty, one in which the most careful experimenters rarely succeed. When success is achieved, the fact is heralded as the essential step in the raising up of a new stock of vaccine more potent in its protective energy than the stocks already in use, the latter being assumed to have become impaired if not effete. We do not believe that this assumption is justified, and, without entering upon the theoretical question of the possibility of converting smallpox into cowpox, we must express our sense of the dangers almost inseparable from attempts to variolate the cow and from the use on the human subject of the virus resulting from a successful attempt.

Nobody need be told that smallpox is communicable by effluvium as well as by actual contact. The virus used in the variolation of the cow is manifestly dangerous to the persons concerned in the experiments, and it may easily become dangerous to others, owing to some laxity or oversight. But, granting that this danger is escaped, who can assure us that the pocks formed in consequence of the inoculation do not contain some of the original variolous contagium in a condition capable of giving rise to smallpox?

The supposition that they may contain it has been entertained by good observers and good reasoners.

It would be warrantable to brave these dangers if it had been proved that the vaccine in use at any given time had really grown too feeble to be relied on as a protective against smallpox, but we do not believe that this has ever been the case. True, the virus employed in a particular series of vaccinations may show weakness, but it is usually susceptible of regeneration, and in the few instances in which this proves not to be the case it can be superseded by vaccine from some other series, for the whole world's supply is in no danger of simultaneous degeneration. Therefore we believe that variolation of the cow should not be encouraged.

VARIOLOUS AND VACCINAL SUSCEPTIBILITY.

Almost all general practitioners of medicine of considerable experience must have met with cases in which it was difficult to account for the apparent insusceptibility or the excessive susceptibility of individuals to smallpox or vaccinia, for the variable duration of the protection afforded by vaccination, or for the somewhat abrupt termination of the immunity furnished either by vaccination or by a previous attack of smallpox. Hardly any great variolous epidemic completes its course without exemplifying almost everything that is unusual as regards these matters. We see men die of smallpox who had been supposed to be proof against it by virtue of having already had it; very rarely we see those escape it, in spite of undoubted exposure, who are not known to have been protected. We meet with persons whom it seems almost impossible to vaccinate with success, but in whom after a time vaccinia is produced with the usual facility. In addition, we encounter subjects in whom we can produce typical vaccine pocks repeatedly and at short intervals.

All this is puzzling; of course, and the facts that tend to throw doubt on the protective power of vaccination in certain instances are apt to induce in the mind of the observer a state of doubt as to the efficiency of the vaccine with which he is working. But generally one can dissipate any such doubt by comparing the exceptional results

with those obtained in the great majority of cases from the use of the same virus. Yet this question of the efficiency of the vaccine comes up for discussion every now and then, as it did recently apropos of some curious facts reported by M. Joseph Belin at a meeting of the Medical Society of the Paris Hospitals (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris*, May 18th). Our own decided impression is that what happens in these unusual cases is due rather to variations of susceptibility than to any defect of the vaccine employed.

AN OLD ANTISEPTIC REVIVED.

Oil of turpentine, commonly called "spirits of turpentine," is the substance that we have in mind. Long before the germ theory of disease was anything more than the fragmentary product of an individual imagination here and there—certainly long before the antiseptic routine came into vogue—it was not unusual for the physician to rub oil of turpentine on his hands before making a post mortem examination, and he did it in the conviction that he was thereby protecting himself against cadaveric poisoning. The balsamics have indeed been recognized as efficient against putrefaction since the most ancient of historical periods, and it was not unnatural that in times past frequent recourse should be had to oil of turpentine, for it was a substance almost always and everywhere easily obtained, hardly a household being without it.

It has lately been particularly recommended by M. Fabre, of Lyons, before the Paris Academy of Medicine (*Semaine médicale*, June 7th), in the treatment of streptococcus puerperal infection. M. Fabre, who has used it both topically and by the mouth, regards it as superior to other antiseptics in this affection. So long as the infection remains local, he contents himself with bathing the interior of the uterus with "terebinthinated water," made by adding to a quart of sterilized water about half a fluid ounce of oil of turpentine dissolved in its own volume of alcohol. When the infection tends to become generalized, he administers the drug by the mouth and subcutaneously. There is no objection, he finds, to giving a drachm daily by the mouth and half a drachm under the skin. For the subcutaneous

administration, however, he prefers the employment of a "terebinthinated serum," prepared by adding to a quart of sterilized artificial serum about a drachm and a quarter of oil of turpentine with the same amount of strong alcohol. A single injection may consist of about six ounces of this liquid, containing about fifteen minims of oil of turpentine. We may suggest that the favorable action of the drug is perhaps not altogether due to its antiseptic properties.

CONGENITAL PROTRUSIONS OF THE BRAIN AND MENINGES.

Billroth divided all cases into two principal groups, namely, exencephaly and cephalocele, the first being the result arising from a general error in the development of the skull, while the latter is due to a partial or local developmental failure. In exencephaly there is an extensive gap in the vault and the remainder of the skull is microcephalic, the brain protruding in varying degrees; although feebly developed as a whole, the ventricular spaces are generally distended with fluid. In cephalocele the opening in the skull is circumscribed and the sutures are generally widely separated, although in some rare cases a microcephalic condition is present. The brain is more or less normal, although occasionally the ventricles are distended with fluid. That cephaloceles are not confined to man is proved by several recorded instances of a similar condition in lower animals. Norsa Gurrieri has described a case of encephalocele in the embryo of *Mus decumanus vel albinus*. He points out that the developmental error involves the bones of either cartilaginous or membranous origin, and that the primary cause is the atrophic condition of the bone, while the ectopia of the brain is a secondary result. Other congenital defects are frequently present, especially spina bifida.

Upon careful microscopical examination of the tumors removed by operation, or post mortem, Lyssenkow found scattered nerve cells, fat cells, fibrous tissue, striated muscle, and vessels, representing, therefore, the products of the ectoderm and of the mesoderm. He also observed that there was often an intimate union between the cephalocele itself and the overlying integument, and in consequence of these findings he formu-

lated the theory that the majority of cephaloceles were in reality cephalomata, or true teratoid growths. He further added that cephaloceles resulted from an incomplete cutting off of the neural epiblastic tube in the head region of the embryo, accompanied by an irregular development of the intervening mesoblast. The defect arises in the early stages of embryonal life, not later than the second or third week. In more embryological terms, the theory advanced states that a cephalocele is the result of an incomplete cutting off of the neural canal in the head region of the embryo from the overlying epiblast, with consequent fusion of the primary neural tube with the primordial mesoblastic membranous cranium, and with the overlying epiblastic surface layer, from which the epidermal portion of the scalp is developed. In consequence of the localized fusion between the primordial membranous cranium and the epidermal coat, the outer dermic coat, from which the membranous skull is formed, fails to develop. Bony defects therefore exist, and through them the brain matter protrudes, the projecting portion frequently being adherent to the skin and containing not only epiblastic elements, but also mesoblastic tissue from irregular occlusion of the mesoblast, as is shown by the presence of striated muscle and so forth.

This teratological explanation of Lyssenkow's accounts more satisfactorily for the cephaloceles which are met with in the nasofrontal region than for those in other situations. The tumors occupy the middle line from the nasal frontal region in front to the occiput and foramen magnum behind. In the nasal frontal region only is there any exception to this rule, the defect being situated between the nasal process of the frontal bone and the nasal bones; in other words, the nasofrontal variety, or, on the inner side of the nose, the nasoorbital, or beneath the nasal bones, the nasoethmoidal type. The tumor may also project through a deficiency in the cartilaginous base, either through the cribriform plate of the ethmoid or between the presphenoid and the basisphenoid, or between the basiocciput and the basisphenoid, the hernial protrusion forming a polypoid projection into the nose or into the nasopharynx.

Cephaloceles vary greatly in size, and, although in the frontal region they are usually small, they not infrequently attain a size equal to that of the remainder of the child's head when they develop in the occipital region. In a case observed in St. Bartholomew's Hospital (Rawling, *St. Bartholomew's Hospital Reports*, 1904) the cephalocele was placed over the anterior fontanelle, and hung downward over the left temporal and frontal regions. The baby was but twelve days old, and yet the tumor was larger than the rest of the head. The skull was, as a whole, microcephalic; fluctuation was obtained in the tumor, but there was no pulsation. The overlying skin was adherent, thinned, and inflamed. In this case an attempt was made to reduce the swelling in size and to protect and improve the condition of the overlying integument. These results being obtained, the patient was removed, and no further history was obtainable.

This same writer points out that it is frequently, almost usually, impossible to determine whether the tumor contains brain matter or not, since mere fluctuation and translucency are both deceptive, and several cases are recorded in which an operation was performed under the impression that the case was a pure meningocele, and in which brain matter was found to form the base of the tumor. When the tumor is large, when the skin is adherent, when no pedicle is present, when fluctuation and pulsation are absent, when the tumor is of firm consistence, and when symptoms of brain irritation are present, brain matter is almost certain to take a large share in the formation of the tumor. On the other hand, it is not unusual to find that the brain projects markedly outward without leading to any symptoms of irritation; fluctuation and translucency are also not reliable signs, since the brain substance may either occupy the base of the tumor or be so thinned by ventricular distention that a mere shell of brain matter lies under the scalp covering. Undoubtedly, therefore, as Rawling points out, the great majority of cephaloceles contain either pure brain matter or the mixed epiblastic and mesoblastic elements described by Lyssenkow. Complete reduction of the tumor, even when small, can rarely be accomplished; pulsa-

tion is usually absent, but an increase in size during straining can generally be detected.

Some other interesting points are illustrated by the following cases: Ssamoylenko reports two cases (*Beiträge zur klinische Chirurgie*, xl, 3), in the first of which the child, one day old, presented a tumor of the frontonasal variety. An operation was performed, and for ten days all went well. On the eleventh day symptoms of meningitis developed, and death resulted. The post mortem showed the anterior fontanelle small, the ventricles distended, and the basal part of the brain the seat of a purulent meningitis. There was a small hole between the frontal and nasal bones, through which a tubular prolongation of dura and of brain projected. An examination of the parts removed showed that the tumor consisted of the following layers from without inward: Skin, dura, arachnoid, pia, and glial fibres. The second case was that of a boy, one day old, the brother of the other patient, born seven years later, five sound children intervening. The tumor was also of the nasofrontal variety, but consisted of two distinct parts—the one reducible, fluctuating, and translucent, the other firm, irreducible, and containing brain matter. No bad symptoms resulted on attempts at reduction, and no treatment was adopted.

A patient with occipital cephalocele was admitted into St. Bartholomew's Hospital (Rawling, *loc. cit.*) in 1896. The child was three months old, and presented a tumor of the size of an orange, which was situated between the external occipital protuberance and the base of the neck. The mass was pedunculated, the stalk being of about the size of a four shilling piece in circumference. It was soft, translucent, and irreducible and swelled upon straining. An attempt at removal was carried out, and after the outermost layers were incised, three ounces of cerebrospinal fluid escaped. A second tumor was then found occupying the base of the projecting mass. This was also punctured, and more fluid escaped. Both sacs were cut away, and the wound was stitched up. Death occurred two days later, preceded by convulsions, retraction of the head, and pyrexia. The post mortem showed that the fontanelles and sutures were wide open, the anterior fontanelle

being four inches from side to side, and two and a half from before backward, and the bones of the vault markedly thinned. In the subdural space there was a quantity of free fluid, but there were no signs pointing to a meningeal infection beyond the fact that the pia mater was oedematous. The brain itself was soft and diffuent, the convolutions were flattened, and the ventricles were distended. There was a broad gap in the occipital bone, extending from the occipital protuberance into the foramen magnum, and in this region the cerebellum bulged outward. The case is of special interest as it illustrated two points on which great stress should be laid; that in large cephaloceles brain matter is almost invariably present, and that the occipital cephaloceles (below the external occipital protuberance) nearly always project through a median cleft, which extends into the foramen magnum.

An interesting case of basal hernia has been recorded by von Mayer (*Beiträge zur klinische Chirurgie*, vii) in a child three days old. The growth, projecting into the right nostril, was covered with mucous membrane, transparent, exuding serum, encrusted with scabs, pedunculated, and resembling in many respects an ordinary nasal polypus. There was no increase in size on straining. The possibilities were fully recognized, and all necessary precautions were taken. The right half of the nose was turned back as a flap, the tumor ligated and removed, and the cavity packed with gauze. In spite of all antiseptic precautions, death occurred six weeks later, though no symptoms of meningeal infection became evident. The post mortem revealed an oval hole in the left half of the cribriform plate of the ethmoid, through which the dura mater projected and to the edges of which the membrane was adherent. The pedicle of the polypoid outgrowth contained ganglion cells and nerve fibres, while the part removed showed, from without inward, mucous membrane, dura mater, arachnoid, pia, and glial tissue.

As to the operative treatment, von Bergmann divides the cases into two principal groups: The first class comprises "inoperable" cases, this feature being made evident by association with premature synostosis and microcephaly, hydro-

cephalus, and marked deformity, or when the tumor is situated below the external occipital protuberance. The "operable" class is represented in cases with limited protrusion and none of the above mentioned defects. As pointed out by Rawling, this practical classification excludes the great majority of cephaloceles from any radical surgical interference, and the cases that remain are but few in number, and are almost entirely limited to the nasofrontal variety. Even in this class any radical operation is carried out under great disadvantages, since the difficulty of keeping the area aseptic is sometimes insuperable. A perusal, moreover, of the recorded cases in which operative treatment has been adopted shows a very high mortality, and though the patient may recover from the operation, the late results are still more unsatisfactory. On the other hand, it must be borne in mind that all palliative measures fail to produce any benefit except in the mildest of cases, and that nearly all the patients who are not surgically treated die at an early age. Risks, therefore, must be taken if a successful result is to be attained.

In order to fill up the opening in the skull, Lyssenkow advised an osteoplastic operation, the flap being turned down from the skull above the gap, consisting practically of the external table only. The periosteal surface becomes internal when the flap is in position, the fragment of bone being suspended by the continuity of the periosteum. He reports seventy-two cases thus treated, with thirty-seven recoveries from the actual operation. König and von Bergmann are opposed to the osteoplastic method on the grounds that the extreme thinness of the skull does not usually allow of the splitting off of the external table, and that even when this method is feasible, the fragment generally necroses. Transplantation of animal bone and silver and celluloid plates have all been employed with no great amount of success. Ssmoylenko proposes paraffin or vaseline injections as a means of filling up the gap in the nasofrontal variety of cephalocele. If no radical treatment is adopted, the tumor, in the majority of cases, tends to increase in size, and the opposite half of the brain lags behind in its rate of growth, owing to the

diminished resistance offered to the brain in the region of the gap. The edges of the gap become thinned and everted from pressure, and the later any surgical treatment is adopted the greater are the local disadvantages. From an operative point of view, however, von Bergmann's classification affords a sound basis on which to act, and an open operation is preferable to mere aspiration in those cases where the gap is small and where the general conditions are favorable.

CHARLES GREENE CUMSTON.

AGAIN THE ALLEGED LABORATORY CREATION OF LIFE.

As we go to press accounts are received of certain experiments by Professor Burke, of the University of Cambridge, in which exposure of a gelatin culture medium, supposed to be sterile, to the action of radium has resulted in the appearance of minute bodies which may or may not be living organisms. Most judiciously, Professor Burke does not commit himself as to their nature, though he maintains that they are different from anything seen before, and apparently inclines to the view that they are bacteria, though admitting that they are soluble in warm water. One of his colleagues, Professor Woodhead, is reported as disposed to look upon them as crystals. Whatever further investigation may prove them to be, we think it safe to assume that they are not living organisms called into being by radium or any chemical or physical agent, much as the wondermongers of the press may itch to establish such an origin for them.

DEATH AFTER A PROTECTIVE INOCULATION.

The recent occurrence in New York of a death shortly after the prophylactic injection of diphtheria antitoxine—undoubtedly a pure coincidence, as Health Commissioner Darlington has suggested—should be looked upon as in no way discouraging our use of antitoxine. No protective measure directed against a specific disease will ever enable us to guarantee longevity or even promise the subject exemption from speedy death from one cause or another.

FOURTH OF JULY TETANUS.

It is none too early to remind physicians in general to exhort heads of families to keep the deadly toy pistol out of the hands of the youngsters. It is now so well known to be a prolific source of tetanus that any omission to caution people against its use is nothing short of reprehensible.

News Items.

NEW YORK.

Changes of Address.—Dr. J. Bergen Ogden, from 419 Boylston Street, Boston, to 1 Madison Avenue, New York; Dr. J. N. Teeter, from Utica, N. Y., to 169 Washington Park, Brooklyn, N. Y.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending June 17, 1905:

	June 17.		June 10.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	746	31	770	18
Diphtheria and croup	281	31	322	30
Scarlet fever	142	5	162	13
Smallpox	1	..
Chickenpox	108	..	120	..
Tuberculosis	373	162	339	167
Typhoid fever	45	13	49	10
Cerebrospinal meningitis	68	42	52	57
	1,763	284	1,805	295

Personal.—In our issue for June 17th, on page 1205, the name of the resident physician of the Willard Parker Hospital was accidentally printed as Lynch. To many of our readers it will be needless to point out that Dr. Louis Fischer desired to express his thanks to Dr. Henry L. Lynah.

The Late Dr. John H. Hinton.—At a stated meeting of the Medical Association of the Greater City of New York, held June 12, 1905, the following resolutions were adopted:

Resolved, That by the death of Dr. John H. Hinton this association has lost a distinguished and honored member.

Resolved, That we extend to the bereaved family our profound sympathy for them, in this, the time of their sorrow. (Signed) R. E. Van Giesen, chairman; P. Brynberg Porter, J. Blake White, committee.

Appointments at St. Vincent's Hospital.—At a meeting of the medical board of St. Vincent's Hospital, held June 13, 1905, the following appointments and promotions were made: Dr. Edward L. Keyes, Jr., visiting surgeon; Dr. Charles F. Fitzgerald, assistant visiting surgeon; Dr. William C. Lusk, assistant visiting surgeon; Dr. William M. Ford, acting assistant visiting surgeon; Dr. John J. Morrissey, assistant visiting physician; Dr. Peter Murray, assistant visiting physician.

PHILADELPHIA.

The Examinations of the Pennsylvania State Board of Medical Examiners will be held in Philadelphia on June 26th, 27th, 28th, and 29th.

Marriages.—Dr. George A. Ulrich and Miss Hester D. Ralston were married on June 10th.

Dr. Morris H. Lindall and Miss Elizabeth M. Hall were married on June 10th.

Charitable Donations.—Dr. and Mrs. George Woodward, Randal Morgan, and Stephen Greene have contributed \$5,000 each to the Germantown Hospital.

Held for Criminal Malpractice.—The coroner held Dr. Horace Ladd, of 1524 Arch Street, and Mrs. Mary Preston, of 1202 North Hutchinson Street, for appearance at the inquest on the body of Mary Diegan, who was certified to have died of acute peritonitis with sudden heart failure.

Scientific Society Meetings for the Week Ending July 1st.—Tuesday, June 27th, Northwest Medical Society; Philadelphia Neurological Society. Wednesday, June 28th, Philadelphia County Medical Society. Friday, June 30th, South Branch, Philadelphia County Medical Society.

Accident to Ambulance.—While responding to a hurry call on June 12th the ambulance of the Chester Hospital, at Chester, Pa., collided with a large wagon and was overturned. The driver of the ambulance was instantly killed and the resident physician of the hospital, Dr. Henry Homer, was seriously injured.

The Prizes Awarded in the Department of Veterinary Medicine of the University of Pennsylvania are: The J. B. Lippincott Prize of \$100, awarded to the member of the graduating class, who, in the three years spent in the veterinary department of the university, attains the highest general average in examinations; to Ezra Strickland Deubler. A prize of an écarleur, offered by a friend of the department to the member of the second year class who passes the best examinations in veterinary anatomy; to Stephen Lockett.

The Health of the City.—During the week ending June 10, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Malarial fever	2	0
Typhoid fever	134	11
Scarlet fever	26	1
Chickenpox	53	0
Diphtheria	69	8
Cerebrospinal meningitis	2	0
Measles	83	2
Whooping cough	32	2
Tuberculosis of the lungs	35	53
Pneumonia	27	23
Puerperal fever	1	0
Tetanus	1	0

The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 9; dysentery, 1; diarrhœa and enteritis under ten years, 25. The total mortality was 422, in an estimated population of 1,438,318, corresponding to an annual death rate of 15.26 per 1,000 population. The total infant mortality was 91; under one year, 73; between one and two years, 18. There were 24 still births, 9 males and 15 females. On June 6th the thermometer reached a maximum of 90°, with a relative humidity from 72 to 84. A thunderstorm in the afternoon caused a fall of 20° in the temperature and the remainder of the week was very comfortable. There was a thunderstorm on the 7th also. The total precipitation for the week was 0.53 inch.

Wills Hospital Staff.—At the meeting of the Board of City Trusts, held June 14th, Dr. McCluney Radcliffe was elected executive officer of the Wills Eye Hospital for one year, beginning July 1st. Dr. Harold G. Goldberg was elected pathologist, and Dr. William G. Schlindwein was elected resident surgeon for one year.

The Quarterly Meeting of the Medical Club was held in the Hotel Walton on June 16th. The medical publishers were the guests of the club.

Representatives of the firms of P. Blakiston's Sons Company, J. B. Lippincott Company, Lea Brothers and Company, O. B. Saunders and Company, and E. B. Treat and Company were present.

The State Board of Health Appointed.—Governor Pennypacker has appointed Dr. Samuel T. Davis, of Lancaster; Dr. Leonard Pearson, of Philadelphia; Dr. Adolph Koenig, of Pittsburgh; Dr. B. H. Warren, of West Chester; and Dr. Lee Masterson, of Johnstown, members of the State Board of Health as advisers to the Commissioner of Health, Dr. Samuel G. Dixon, whose appointment we recently noticed.

A Reception to the Class of Nurses, recently graduated from the Samaritan Hospital, was given by the board of women managers on the evening of June 16th. The commencement exercises were held on the evening of June 15th, at which time Miss Margaret J. Maloney, Miss Jean Bricker, Miss Fannie Mathews, Miss Kathryn Nilan, Miss Una Bardsley, Miss Edna Moore, Miss Charlotte Darlington, Miss Maud A. Hayes, Miss Wynnie Biggard, and Miss Emily Turville received diplomas. Dr. Wilmer Krusen delivered the address.

The Annual Meeting of the Priestly Club was held in the Harrison Laboratory of the University of Pennsylvania on the evening of June 10th. It was urged at that time that an endowment fund be established for a chair of chemical engineering. Mr. William Bower offered to give \$200 yearly for the purpose. The Priestly Club prize was awarded to John Morris Weiss. The following officers were elected: President, Dr. George Tyson; vice-president, Dr. Howard Graham; treasurer, Dr. James Gillinder; secretary, Dr. T. P. McCutcheon; librarian, Dr. B. L. Wallace; executive committee, Dr. William Rowland, Dr. J. Merritt Matthews, Dr. L. P. Morgan, and Dr. William Bowers.

Commissioner of Health of Pennsylvania.—The announcement was made on June 7th that Governor Pennypacker had appointed Dr. Samuel G. Dixon, president of the Academy of Natural Sciences, Commissioner of Health of Pennsylvania, at a salary of \$10,000 per annum. In a newspaper interview Dr. Dixon is quoted as follows:

"Prevention and protection are the two sides of sanitation, and I need not say more at this time, perhaps, than to point out that I shall begin at once to create the organization necessary to carry the law into effect, that I may secure cooperation, and not antagonism, from corporations and individuals.

"We need time and patience to accomplish anything; but, with this understood, I hope that we can make Pennsylvania a model State from the point of view of public health. I appreciate the honor of the selection, the encouragements I have already received, the proffers of cooperation on the part of my scientific and professional friends, and the thing to do now is to get to work."

Dr. Dixon was born on March 23, 1851. He studied law and was admitted to the bar in 1877. In 1886 he graduated from the medical department of the University of Pennsylvania. After

a year or two spent in study abroad, Dr. Dixon returned to Philadelphia and was appointed professor of hygiene in the University of Pennsylvania, and while holding that chair organized the Auxiliary Department of Medicine, which has since been abandoned. In 1889 Dr. Dixon resigned from the University of Pennsylvania. In 1891 he was made a curator in the Academy of Natural Sciences; in 1892 an executive curator, and in 1896 president.

Personal.—Dr. William S. Wadsworth was operated upon on June 15th for appendicular inflammation at the German Hospital.

Dr. John H. Musser has been named as one of a representative group of citizens to advise with the mayor of the city in his attempt to place the government of the city on a business basis.

Deaths.—Dr. David Dennison Stewart died on June 13th in spite of an operation for excision of the appendix. Dr. Stewart was 46 years of age. He graduated from Jefferson Medical College in 1878. He was a fellow of the College of Physicians, a member of the Philadelphia County Medical Society, and of the Medical Society of the State of Pennsylvania. At the time of his death he was consulting physician to the Kensington Hospital for the Diseases of Women.

Dr. S. S. Finkbeiner died at Parkerford, Pa., on June 11th. Dr. Finkbeiner graduated from Jefferson Medical College in 1865.

Commencement at the University of Pennsylvania.—Exercises incident to commencement at the University of Pennsylvania began on June 8th. The baccalaureate sermon was delivered on June 11th. The public commencement exercises were held on June 14th, at which degrees were awarded in all departments. The Reverend George Harris, D. D., LL. D., president of Amherst College, delivered the oration. The degree of Doctor of Medicine was awarded to the following:

Matthew Howard Ames, Harry Stanley Bachman, Walter Kreider Baer, Henry John Bartle, Jr., William Lawson Berst, Ernest Sydney Bisbee, Egil Boeckmann, Peter Boyesen, Samuel Bradbury, third, Erick von Buddenbrock, William Michael Bunce, Charles Winfield Buvinger, Ethan Allen Campbell, John Moore Campbell, Harry Schwartz Crouse, James Gerald Cullen, James Henry Culpepper, Albert Burrows Davis, Charles Walter Delaney, William Thomas Dempsey, Frank Dake Dickson, Henry Dintenfuss, Eldridge Lyon Eliason, Thomas Evans, Jr., Charles Mackall Fisher, Oscar Edwin Fox, Fred Leon Gage, Charles Herbert Gerhard, Nate Ginsburg, Arthur Bruce Gill, Clarence Hamilton Gray, William Henry Greiss, Don Carlos Guffey, William Frank Gullfoyle, Jr., George Donald Guthrie, John Andrew Hardenbergh, Walter Samuel Hargett, Oscar Freer Hills, Harry Clyde Hoffman, Charles Jack Hunt, Samuel Harvey Iams, Frank Stewart Inksetter, Moses Jacob, Milton Boyd Katzenstein, Walter Elmo Kelton, John William Kirschner, Orion Frank Konantz, Charles Alpheus Lauffer, George Malcolm Laws, John Leedom, Presley McCance Lloyd, Oscar Lotz, Tom Odum Luckett, William Marshall, Jr., Robert Francis Mathews, Jr., John Weigle Mehring, Thomas Elwood Mendenhall, Henry Martyn Metcalf, Hubert Livingstone Miller, Albert William Moore, Joseph Leslie Moore, William Frederic Moore, Stirling Walker Moorhead, Timothy Joseph Moran, David Blair McIntire, Daniel Charles McLaughlin, Charles William Naulty, Jr., Percival Nicholson, Thomas Aloysius O'Brien, David Stanislaus O'Donnell, Alexander Hay O'Neal, Samuel Torrey Orton, Hubley Raborg Owen, Ar-

thur Hilton Paine, Robert Lee Payne, Jr., Arnaldo de Moraes Pedroso, Ferdinand Mitchell Perrow, George Morris Piersol, Lester Lovett Powell, John Williamson Price, Jr., Frederick Prime, Jr., Mahlon Richardson Raby, Edward Urbane Reed, John Jacob Repp, Dennett LeRoy Richardson, Willis Read Roberts, Jr., Harold Eugene Robertson, James Coburn Rogers, Harry Abraham Schatz, Howard Gustav Schleiter, Joseph Schenberg, Herbert John Schmyer, William Magill Schultz, George Meade Settle, Robert Vance Stewart, Marvin Price Stone, John Frank Streeter, Henry Hurlburt Tomlin, Norris Wistar Vaux, Charles William West, Edgar Lee West, Leslie Marshall Westfall, Edward Clendenning White, Otto George Wiedman, Edward Mercur Williams, Robert Edward Williams, Fred Bailey Wilson, Tom Bush Wofford, William Wellington Woodward.

GENERAL.

Richmond, Va., Academy of Medicine and Surgery.—The subject for discussion at the June 27th meeting of this body is The Menopause, which will be opened by Dr. W. L. Peple and Dr. J. N. Upshur.

Miami Medical College, of Cincinnati, O., has graduated the following in medicine:

Theodore Bange, Mora Simeon Bulla, George Wylie Cline, Louis M. Cusher, David Judkins Dickson, Sherwood P. Garrison, Raymon E. Gaston, George A. Haveman, John Wesley Hutchens, John Walter Irwin, William S. Kautz, George Goodhue Kineon, Michael Louis Landman, Michael A. O'Hare, Jacob C. Poling, William Walter Sauer, Miriam Schaar, Thomas P. Scott, A. B., Frederick J. Smith, Ralph Henry Smith, Martin Harley Urner, A. B., Charles Jefferson Woods.

Of Interest to Navy Medical Officers.—In a recent decision, says the *Army and Navy Medical Journal*, for June 17, 1905, upon the pay to which Medical Director Farwell, United States Navy, retired, was entitled during the period when he was on active duty on shore under the provision of the Act of June 7, 1900, the comptroller of the treasury holds that the medical director "is entitled while on active shore duty to old navy pay at the rate of \$4,000 per annum, provided by Section 1556, Revised Statutes."

American Laryngological, Rhinological, and Otological Society.—At the eleventh annual meeting of this society, held in Boston, Mass., June 5, 6, and 7, 1905, the following officers were elected for the ensuing year: President, Dr. James E. Logan, of Kansas City, Mo.; vice-presidents, Dr. Thomas H. Halsted, of Syracuse; Dr. William L. Ballenger, of Chicago; Dr. H. Bert Ellis, of Los Angeles., and Dr. Henry L. Myers, of Norfolk; secretary, Dr. Wendell C. Phillips, of New York; treasurer, Dr. Ewing W. Day, of Pittsburgh; council, Dr. Frederic C. Cobb, of Boston; Dr. James F. McKernon, of New York, and Dr. H. W. Loeb, of St. Louis.

North Carolina State Board of Medical Examiners.—The forty-third annual session of the North Carolina State Medical Examining Board was held in Greensboro, N. C., May 17th to 25th, inclusive. One hundred and thirty-three graduated physicians were examined for license. Of this number one withdrew, forty were rejected, and ninety-three were granted license. The board submitted a resolution to the State Medical Society reciting the fact that in their forty-two years' ex-

perience almost all of the failures before the board of examiners came from men who had deficient preliminary education and urged the importance of a proper preliminary education prior to entering upon the study of medicine. The State society unanimously approved of this action.

The Gordon Dinner in Portland, Maine.—One of the most pleasing incidents in the history of the profession in Maine occurred on June 6th in the beautiful casino at Riverton, where a dinner was given by his professional friends, both in Portland and elsewhere, to Dr. Seth C. Gordon, of Portland, to commemorate his fiftieth year of medical practice. The attendance was representative of the country. Old friends from all parts of the United States were either present in person or sent personal letters to congratulate Dr. Gordon upon his long and unusual term of service. Not the least pleasant feature of the dinner was the presentation to him of an exquisite silver service.

Statement of Mortality in Chicago for the Week Ending June 17, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's midyear populations—1,990,750 for 1905 and of 1,932,315 for 1904:

	June 17, 1905.	June 10, 1905.	June 18, 1904.
Annual death rate per 1,000.....	12.01	13.46	10.28
Total deaths, all causes.....	458	514	380
By sexes.....			
Males.....	256	307	212
Females.....	203	207	168
By ages.....			
Under 1 year.....	79	90	57
Between 1 and 5 years.....	60	44	27
Over 60 years.....	87	108	86
Important causes of death.....			
Acute intestinal diseases.....	30	18	24
Apoplexy.....	14	19	15
Bright's disease.....	38	46	37
Bronchitis.....	16	7	70
Consumption.....	60	70	51
Cancer.....	22	19	26
Convulsions.....	9	9	10
Diphtheria.....	8	4	4
Heart disease.....	34	48	30
Measles.....	4	12	1
Nervous diseases.....	15	12	13
Pneumonia.....	55	73	28
Scarlet fever.....	1	1	0
Smallpox.....	3	1	0
Suicide.....	2	10	6
Sunstroke.....	1	1	0
Typhoid fever.....	4	8	3
Violence other than suicide.....	36	28	24
Whooping cough.....	9	8	4
All other causes.....	97	120	93

While the June, 1905, health rate is not up to the record of June, 1904, the improvement during the week—measured by the mortality returns—will bring it higher than the average of the decade. For the elapsed seventeen days the rate is 12.73; for the week it is 12.01 and the average of the decade is 14.00. June, 1904, is the record month of lowest mortality—the rate being 11.02 per 1,000 of the population. Among the important causes of death showing decrease the most notable are pneumonia, 18; consumption, 10; heart disease, 12, Bright's disease and measles, 8 each, and typhoid fever, 4. On the other hand, the acute intestinal diseases show an increase of 12; bronchitis of 9; and diphtheria of 4. Only two suicides were reported during the week—the smallest number in any one week for several years—the average weekly number during the previous ten years being 7.5.

LYON MEDICAL.

May 21, 1905.

Cerebral Syphilis and Injections of Hermophenyl,

By ROQUE and CORNELOUP.

Cerebral Syphilis.—Roque and Corneloup report these four cases. In case 1 the patient had suffered for three years from localized headache recurring at night, and for three weeks from attacks of Jacksonian epilepsy. Thirteen injections of hermophenyl, a total amount of 1.52 gramme, resulted in a complete cure. In case 2 transitory right hemiplegia with great exaggeration of the reflexes and persistent aphasia was cured by 1.52 gramme of hermophenyl administered in thirteen injections. Case 3 was one of general paralysis, which was greatly improved by the same treatment. In case 4 there was a history of hysteria and of syphilis. The patient had a cerebellar tumor accompanied by attacks of Jacksonian epilepsy, with a tendency to walk backward and to the right, and vertigo. No benefit was obtained from injections of hermophenyl. Autopsy revealed a cerebellar tumor as large as an egg, which arose from the meninges and pressed on the right hemisphere. It was cystic and did not appear to be of a syphilitic nature.

REVUE DE MEDECINE.

May, 1905.

1. Youthful Rigidity, By NAGEOTTE WILBOUCHEVITCH.
2. Fungoid Mycosis with Deep and Multiple Ulcerations, Treated and Cured by Soluble Toxines of the Streptococcus of Erysipelas, By MARTIN-ROUX.
3. Delayed Apoplexy of Traumatic Origin. Its Importance from a Medicolegal Standpoint, By MARIE and CROUZON.
4. Contribution to the Study of the Origin of the Pigment in Bronzed Diabetes, and of the Pathogenesis of this Disease, By MARGAIN.

1. **Youthful Rigidity.**—Nageotte Wilbouchévitch gives many illustrations of this condition which puts a child in a vicious circle. The insufficient motion, the condition of chronic asphyxia when the stiffness appertains to the thoracic cavity have a profound effect upon the circulation, upon the entire organic life, and so upon the nutrition of the nervous system. The bad general condition, and the intellectual torpor tend to make such children inactive, and favor the exaggeration of the rigidity. This condition calls for mechanical treatment for passive and active exercise and for massage. Improvement usually takes place slowly, and calls for patience and perseverance. With girls it will be necessary to overcome costal respiration by diaphragmatic. The improvement in the general condition and the intellectual development progress *pari passu* with returning freedom of motion. When their movements become free and extensive, they become wide awake at the same time.

2. **Fungoid Mycosis Treated and Cured by Soluble Toxines of the Streptococcus of Erysipelas.**—Martin-Roux affirms that of the three malignant diseases of the skin fungoid mycosis, sarcoma, and cancer, the first has proved quite sus-

ceptible to treatment with the toxines of the streptococcus of erysipelas. Should subsequent experience confirm that which has already been observed, it will be proper to regard this as the specific treatment for that disease. The living organism should not be used in this treatment, nor should its virulence be increased by combination with other microbes. Its soluble toxine, filtered and heated to 110° to 120°, will be sufficient. It is not even necessary that there should be violent febrile reaction with an attack of cutaneous pseudoerysipelas. Should there be a recurrence of the disease the treatment must be repeated. Sarcoma has been treated successfully by this means in two or three cases. Cancer has never been cured whether the solution was obtained from the living or the dead streptococcus. The author concludes that it is quite probable that further beneficial results will be obtained with the streptococcus of erysipelas.

3. Delayed Apoplexy of Traumatic Origin.—

Marie and Crouzon believe that delayed traumatic apoplexy is due to a cerebral lesion, often hæmorrhagic, and occurring in one who is predisposed to vascular lesions. The idea of delayed cerebral injuries consecutive to traumatism is of great importance from a medicolegal standpoint, and especially with reference to the accidents which occur when men are occupied in their work. A physician who may be called to examine a case of this character should remember that nervous diseases which develop slowly after a traumatism has been received are not always functional; they may be due to an organic lesion, and therefore warrant a prognosis which is grave, both as to life and as to a resumption of occupation. One should endeavor to ascertain whether the nervous disease is due to traumatism alone, or in part at any rate to the influence of a hereditary tendency.

REVUE DE CHIRURGIE.

May, 1905.

1. Tuberculosis and Tuberculous Stenosis of the Pylorus, By RICARD and CHEVRIER.
2. The Surgical Treatment of Hydatid Cysts of the Abdomen, By MABIT.
3. Functional Impotence Following Injuries to the Joints, By MALLY and RICHON.
4. The Surgery of the Heart, By GUIBAL.
5. Tuberculosis of the Coccyx, By CAUBET.

3. **Functional Impotence Following Injuries to the Joints.**—Mally and Richon offer the following conclusions: 1. In every case of functional impotence consecutive to a traumatism of the joints, it is necessary to remember that spinal disease may be associated with the disease of the joints, reflex amyotrophy being the manifestation which is the most apparent and the best known; 2, to the well known symptoms of reflex atrophy, including atrophy, paresis, spasmodic phenomena, diminution of galvanic and faradaic excitability without the reaction of degeneration, we must add diminution of electrical resistance in comparison with the unaffected side; 3, reflex amyotrophy is usually fatal in its results when an effusion of the joints is developed. All degrees of involve-

ment are possible, from simple paresis to complete paralysis; 4, pathological anatomy as well as experimentation have demonstrated that the principal medullary lesion consists in a diminution of the large motor cells in the anterior horns. In the nerves and muscles, in the midst of healthy elements there may be degenerated sensory nerve cords pertaining to the joints, degenerated motor fibres, atrophied muscular fibres, forming the lesions of the reflex arc, and sustaining the theory of Vulpian and Charcot. Centripetal excitation referred to the joints which may change the motor cells of the anterior horns may also change the other trophic centres which preside over the nutrition of the other tissues or circumarticular organs. The medullary lesions are in two different forms or degrees; 5, the idea of reflex amyotrophy of articular origin should hold an important place in general surgical pathology, for it explains the pathogenesis of a great number of joint diseases; 6, there is no necessary relation between the intensity of the articular affection and the gravity of the reflex amyotrophy which it causes, but the more the articular irritation is prolonged the more incurable are the medullary lesions. Reflex amyotrophy is always more severe in its significance for the lower extremity. The more curable the articular lesion, the more curable the reflex amyotrophy. Should the former become chronic the latter will be incurable; 7, electrical exploration enables one to determine the prognosis of reflex amyotrophy. It becomes the more grave as the galvanic excitability is diminished, comparing it with the unaffected side; 8, the benign form of reflex amyotrophy may be treated by faradism or static electricity. Should the spasmodic phenomena become prominent localized faradization would be injurious. Static electricity in its sedative form would be more appropriate. In the incurable forms static electricity is useful to relieve the spasmodic and painful symptoms. Such symptoms contraindicate all treatment which may be violent or forcible. The spasmodic phenomena, including exaggerated tendon reflexes, exaggerated mechanical excitability of the muscles, rapid fatigue with contractures, form the practical guide to the proper direction of treatment.

BOSTON MEDICAL AND SURGICAL JOURNAL

June 15, 1905.

1. An Experimental Study of the Accuracy of Modern Clinical Methods for the Diagnosis of Disorders of the Stomach (*To be continued*),
By HENRY F. HEWES.
2. Individual Factors in Hygiene,
By R. C. CABOT and P. K. BROWN.
3. The Effects of Tobacco Upon the Throat,
By S. W. LANGMAID.
4. Studies on Epilepsy.
(a) Treatment of Status Epilepticus,
By ARTHUR MORTON.
(b) Reflexes in Epilepsy,
By ARTHUR MORTON.
(c) Exhaustion Paralysis in Epilepsy,
By MORGAN B. HODSKINS.
(d) Report on the Hypochlorization Method of the Treatment of Epilepsy,
By ARTHUR MORTON.
(e) Lumbar Puncture in Status Epilepticus,
By MORGAN HODSKINS and ARTHUR MORTON.

2. Individual Factors in Hygiene.—Cabot and Brown assert that it is not possible to formulate rules of hygiene which will be valid for all. We can say that a man must eat something and sleep sometimes, but if we try to be more definite than this we find ourselves on very uncertain ground. The reason for this is that every individual has his own ideals regarding living. The best we can do is to formulate, or rather collect, a number of ways of living that have been found satisfactory by groups of people of a certain build, a certain ideal of life, a certain inheritance, and use them as the types of life that should be led by similar individuals. The authors purpose to collect the statistics necessary for determining some of these typical modes of existence.

3. Effects of Tobacco.—Langmaid concludes that tobacco smoking is not only harmful to the throat as a direct irritant, but that it produces vasomotor disturbances of the pharyngeal mucous membrane by its poisonous effects upon the nervous system.

4. Epilepsy.—Morton considers the treatment of status epilepticus (a) by means of sodium bromide hypodermically and by lumbar puncture. The salt should be used of the strength of thirty grains to the ounce of water. Six ounces of this solution may be injected at one time if it is introduced just below the angle of the scapula. In other localities large injections may be followed by abscess. As a prophylactic against the status the injections are best given as follows: ". . . if certain patients, who are apt to have a series of convulsions or to develop status, have two convulsions in succession they shall at once receive ten hypodermics, twenty minims each, of the sterile sodium bromide solution. In this way the patient receives about 12 grains of the salt early in the attack. If the patient continues to have convulsions, ten of the small hypodermics are given after each convulsion until the patient has received forty injections with the small syringe. These injections may be given in any part of the body for, so far as we have been able to observe, they never give any trouble. This plan of treatment we feel sure has warded off many attacks of status which would have developed if we had followed the old plan of giving drugs by the mouth." The author has employed lumbar puncture in seven cases with varying results. He believes that the procedure is of value in those cases that have increased intracranial pressure. (b) Reflexes. The plantar reflex in most cases was found to be absent or not active directly after the tonic stage, probably due to the unconscious condition of the patient. In the state between the convulsions this reflex is often quite active. The activity of the knee jerk depends upon the degree of exhaustion or irritation produced by a given convulsion in the cortical motor cells. The greater the exhaustion, the less active the knee jerk. (c) Hodskins reports four cases of exhaustion paralysis following epilepsy. (d) Salt poor diet. Morton bases his conclusions on experiments performed on about one hundred and twenty-four patients. These conclusions are: The hypochlorization method controls the convulsions, requiring only about one half the amount of

bromide usually given. It has little or no effect on the general nutrition of the patient. It is apt to cause constipation. It does not furnish enough salt to satisfy the patients' craving. It may be used with success with intelligent patients. It is practically useless in the middle grade of epileptics, as they have neither the desire nor the will power to carry it out properly. A modified salt poor diet, in which about equal parts of sodium chloride and sodium bromide are used in the food may be used to advantage with idiotic and demented patients if their diet can be controlled absolutely. Bromism is comparatively rare. (e) This is a report of the seven cases of lumbar puncture referred to in (a).

By GEORGE W. CRILE.
11. Immunity. Chapter XVII.

1. **Tuberculosis.**—Norris asserts that the basis of the successful treatment of tuberculosis is: First, a constant and unlimited amount of fresh air and sunlight; second, the proper quantity and quality of food, taken at the right time; third, a regulation of the expenditure of bodily energy; anabolism and catabolism being so regulated that the balance sheet shall always show a credit in favor of the former. He gives in detail his methods for treating the most common symptoms of the disease, such as fever, night sweats, hæmoptysis, pain, insomnia, and heart weakness. There is nothing new in the methods he advocates.

2. **Exophthalmic Goitre.**—Elliott reports in detail the history of a patient who suffered from exophthalmic goitre, diabetes, Bright's disease, mitral disease, and retinitis. He attempts to determine what relationship, if any, existed between the different morbid conditions.

3. **The Aortic and Mitral Valves.**—Homans and Burrage have studied the heart valves obtained from forty-two autopsies. They report

their work under three heads: (1) Normal structure of valves and normal variations of structure with age. (2) Degenerative lesions. (3) Acute infections in relation to degenerative lesions. The third part of their paper is of the most practical utility. They thus summarize it: "We can only conclude from our observations on acute infections in degenerate and thickened valves that mucoid and fatty degenerations do not apparently predispose to infection; that 'benign thickenings' do not predispose to infection, though it is hard in the case of the mitral valve to tell whether a thickening is benign or due to repeated acute attacks; that the thickenings in mitral valves when infected are better repaired than in those of aortic valves; and that acute toxæmias do not cause degenerations (at least none that we can recognize) predisposing to infection."

4. **Gastroenterostomy.**—Wathen reviews the general subject of gastroenterostomy. He gives also the latest opinions on the subject, obtained by special correspondence, held by Robson, Czerny, von Mikulicz, Moynihan, Kocher, Murphy, Mayo, Ochsner, Park, and Deaver. From all the evidence thus gathered the author concludes: (1) Some cases of acute and subacute gastric and duodenal ulcer, and many cases of chronic and duodenal ulcer should be treated by efficient stomach drainage into the duodenum or jejunum. (2) Drainage by pyloric divulsion, and by pyloroplasty with its modifications, has not been successful, and these methods are now practically obsolete. (3) Gastroduodenostomy, as modified by Kocher and Finney, may give efficient drainage in many cases, but it should be limited to such patients as cannot be operated on by a posterior retrocolic gastroenterostomy with the anastomosis near the duodenojejunal flexure. (4) Anterior anticolc gastroenterostomy should not be an operation of election, but an operation of expediency and necessity, to give temporary relief, or to meet special abnormal conditions that may contraindicate the posterior attachment. (5) The ideal operation of election must be the posterior retrocolic attachment near the beginning of the jejunum, and at the bottom of the stomach in the pyloric end, thus eliminating the loop. (6) This gives the most efficient drainage, prevents the vicious circle and regurgitant vomiting, leaves stomach and intestine in nearly normal relation, and is followed by better immediate and ultimate results. (7) The intestinal incision should be made longitudinally and not less than two inches long, and the stomach incision of corresponding length, preferably in the oblique direction. An elliptical strip of mucosa should be excised from both stomach and intestinal incision. (8) The anastomosis is best made with a continuous suture (Pagenstecher or silk), using a full curved round-pointed needle. The suture should be applied in double layers, the inner to include all the visceral layers, and unite the cut edges of the opening; the outer, one fifth inch away, to include the serous and subserous layers. (9) Enterenterostomy, or closure by suture constriction or resection of the proximal jejunum or the pylorus is contrain-

dicated. It commits an unnecessary traumatism and leaves a deformity that may cause immediate and subsequent bad results.

7. Turning in Hemiplegia.—Pemberton has examined 36 patients suffering from organic hemiplegia in order to test the assertion of Kidd that in 99 per cent. of cases of hemiplegia: "If a patient in walking turns round to the affected side or more affected side, an organic lesion is present. If he turns to the sound or less affected side the case may be one of either functional or organic affection; a cursory examination will determine which." The author found that only 67 per cent. of the whole number turned to the affected side, 16 per cent. turned to the sound side, and 16 per cent. turned indifferently to either side; a difference of over 30 per cent. from Kidd's figures. If it can be shown that a functional hemiplegic ever turns to the affected side, and observations are perhaps needed to that end, the value of Kidd's deductions is much lessened. While the above findings do not disprove his conclusions, that a man who turns to the affected side is organically diseased, they make that fact applicable as a test to fewer cases, and consequently leave a larger proportion open to other means of diagnosis.

10. Shock.—Cushing concludes: Every tissue and organ has a more or less individual shock producing value and must be individually considered. The amount of shock produced by a given trauma varies according to the amount and special quality of nerve supply involved and the number and intensity of the afferent impulses originated by the injury or operation. Cocaine or eucaine may wholly "block" these shock producing impulses. When one or more of the accessory causes of shock are present the highest possible tax is laid on the surgical judgment of the operator. A precise technics, offering a minimum of exposure and trauma, grafted on a comprehensive grasp of all the factors entering into the operative consideration, are the ideals for which we must strive.

MEDICAL NEWS.

June 17, 1905.

1. The Value of Lumbar Puncture: With Particular Reference to the Diagnosis of Tuberculous Meningitis,
By EUGENE P. BERNSTEIN.
2. The Bacterial and Cellular Examination of the Spinal Fluid in Fifty Cases of Cerebrospinal Meningitis,
By T. W. HASTINGS.
3. Report on Gallbladder Surgery, with Especial Reference to Early Diagnosis and Early Operative Interference in Cholecystectomies, with a Brief Summary of Twenty-eight Cases, Including Six Cholecystectomies (*To be continued*),
By FRANK MARTIN.
4. Adulteration and Substitution,
By GEORGE C. DIEKMANN.
5. Colds, and the Prevention of Colds,
By NEWTON JAMES.
6. The Carbohydrate Reactions of the Paratyphoid or Paracolon Group (Preliminary Communication),
By W. W. FORD.

1. Lumbar Puncture.—Bernstein's paper is based on the examination of 265 specimens of

cerebrospinal fluid. The results are tabulated. There were: (1) Forty-six non-inflammatory fluids. (2) Forty tuberculous fluids. (3) Eighty-four fluids containing the meningococcus. (4) Nine containing streptococci. (5) Three containing pneumococci. It is not feasible to condense such a mass of specific information as the author reports. We note only that he was able to recover the tubercle bacillus in 38 of the 40 cases of tuberculous meningitis. In some of the cases it was necessary to search for several hours before the bacillus was found. The author holds that it has been proved that, rarely, patients suffering from tuberculous meningitis get well.

2. The Spinal Fluid.—Hastings gives in detail the results he obtained from the examination of the spinal fluid in fifty cases of cerebrospinal meningitis. These examinations emphasize the importance of the examination of the spinal fluid in order to differentiate meningismus from true meningitis, and serous from purulent meningitis; the importance of a careful method of examination for cells and bacilli in the tuberculous cases; the value of cytodagnosis in the study of spinal fluids; the similar changes produced in the spinal fluid by the meningococcus and the pneumococcus infections; the readiness with which the diagnosis of epidemic cerebrospinal meningitis may be made with good technics from freshly drawn spinal fluid.

4. Adulteration and Substitution.—Diekmann presents statistics which go to prove that the practice of adulteration and substitution, by retail pharmacists in New York city, is very infrequent.

5. Colds.—James asserts that the majority of colds could be prevented by the sufferers keeping in the open air as much as possible, by their discarding wool next to the skin, and by keeping the nose and throat in a healthy condition. How to do all this is explained in detail.

MEDICAL RECORD.

June 17, 1905.

1. The Carbon Factor in Gout: "Hyperpyræmia,"
By FRANCIS HARE.
2. Removal of the Lens in Myopia,
By JUSTIN L. BARNES.
3. Rectal Injections of Large Doses of Sodium Salicylate in Cerebrospinal Meningitis,
By A. SEIBERT.
4. The Medical Phases of the Immigration Legislation,
By VICTOR G. HEISER.
5. Masturbation in Childhood,
By AUGUST ADRIAN STRASSER.
6. Saw Palmetto,
By I. L. VAN ZANDT.

1. Gout.—Hare believes that acute articular gout is due to the accumulation in the blood of an excess of "carbonaceous" materials. To this supersaturation of the blood with carbonaceous material the author gives the name hyperpyræmia. This hyperpyræmia leads to an accumulation of uric acid in the blood. The author's theory may therefore be regarded as an attempt to explain how "free" uric acid gets into the blood.

2. Removal of the Lens.—Barnes asserts that removal of the lens is a justifiable operation in

certain well selected cases of myopia. He reports in detail one case in which vision was increased about two and one half times by the procedure he advocates. The Fukala operation is, generally speaking, the operation of choice. The author reviews the history of this method of treatment and discusses its justifications, indications, contraindications, and technics.

3. **Cerebrospinal Meningitis.**—Seibert reports five cases of cerebrospinal meningitis in which recovery took place in consequence, he believes, of the patients receiving large doses of sodium salicylate per rectum. These five cases constitute practically his total experience with this method of treatment. It is essential that large doses of the drug be given. Thus a child of 22 months received 150 grains of sodium salicylate in sixty hours. Fifteen grains, dissolved in a tablespoonful of warm water, should be given at a dose.

6. **Saw Palmetto.**—Van Zandt has had good results from the administration of saw palmetto in inflammatory conditions of the bladder, prostate, throat, and tonsils. He employs a drachm of the fluid extract four times a day.

AMERICAN MEDICINE.

June 17, 1905.

1. The Relations of Public Health Science to Other Sciences, By WILLIAM T. SEDGWICK.
2. Knee Injuries, and How to Manage Them, By DE FOREST WILLARD.
3. Tropical Anæmia, By M. J. ROSENAU.
4. The Present Status of Röntgen Ray Therapy in Dermatology, By JULIUS HIRAM COMROE.
5. Encephalitis and Other Nervous Affections Complicating Scarlatina, By JOHN H. W. RHEIN.
6. The Progress of the Sanatorium Movement in America, By WILLIAM H. BALDWIN.

2. **Knee Injuries.**—Willard gives the following advice regarding the treatment of some of the so called lesser knee injuries: (1) Apparently slight injuries of the knee often prove more lasting and annoying than those of a more positive nature, as fracture or dislocation. (2) Every injury of the knee should receive careful examination, since laceration of ligaments or of circumarticular tissues, or displacement of semilunar cartilages, or of loose bodies, may have occurred. Obscure fractures, also, are not uncommon. (3) Every injured knee requires rest during its acute inflammatory stage; rest in bed, fixed dressings, and crutches are needful. Heat and cold are two powerful agents in aborting a threatened inflammation. (4) Adhesive plaster strapping is of great value in securing partial restraint of a knee and in producing absorption of effusion. Restricting apparatus should be used with discrimination. (5) Blood clots in the joints should be removed by incision and flushings. (6) Effusions, if large, should be removed by aspiration, or incision followed by weak iodine injection. (7) Displaced semilunar cartilages should be stitched in position, or removed. Loose cartilaginous bodies should be removed. (8) Motion is the normal condition of

joints, consequently massage and voluntary motions should be instituted as soon as the inflammatory stage has passed. Neglect of this precaution may result in a neuromimetic patient and a chronic cripple. (9) Sensitive neurotic knees should not be mistaken for diseased ones. (10) Complete primary rest during the inflammatory stage, followed by massage, voluntary and involuntary movements, gymnastic exercises, hot air treatment, hot and cold douchings, etc., are the best means at our command for preventing ankylosis. (11) Should ankylosis follow, forcible straightenings, tenotomies, osteotomies, etc., may be required.

3. **Tropical Anæmia.**—Rosenau devotes his paper to the two great causes of tropical anæmia, malaria and uncinariasis. The malaria of the tropics is the æstivoautumnal fever. This type of malaria is controlled by quinine only to a limited extent. Hence the problem is to limit the disease rather than to cure it. Uncinariasis may be acquired either through the mouth or through the skin. In either case the worm finally settles in the small intestine. Thymol is practically specific in its action against the parasite.

5. **Nervous Affections Complicating Scarlatina.**—Rhein reports the case of a child of nine years who died of scarlatina. During life there were no symptoms of meningitis or brain irritation, yet at autopsy was found evidence of beginning pachymeningitis and encephalitis. The most common complications of scarlatina on the part of the nervous system are hemiplegia and peripheral neuritis. More rarely this disease may be followed by paraplegia, optic neuritis, amaurosis, tetany, pseudoataxia, neuralgia, epilepsy, disseminated sclerosis, Friedreich's ataxia, hysteria, chorea, hydrocephalus, meningitis, and disordered mental states. With the exception of hemiplegia, and imbecility, the prognosis is good, if we exclude rare organic cases, such as Friedreich's ataxia, disseminated sclerosis, and epilepsy. The pathological findings consist of thrombosis, embolism, small cerebral hæmorrhage, rarely abscess of the brain, congestion of the brain, and meningitis, and finally meningitis and encephalitis.

MEDICINE

May, 1905.

1. The History of Panama and the Panama Canal, By EGBERT.
2. The Isthmian Canal Zone, By MCFARLAND.
3. Medical Conditions of the Isthmus of Panama with Other Notes, By CURTIN.
4. How Can the Physician Profit by Preventive Medicine? By TAYLOR.
5. Accouchement Forcé, By BOYD.
6. Civil Malpractice, By TOBIAS.
7. An Orbital Tumor of Ten Years' Standing, By LEENHEER.

5. **Accouchement Forcé.**—Boyd draws the following conclusions: 1, each case must be a study in itself; 2, forced delivery, by whatever method, must be considered a major operation

and should be performed by one trained in obstetric surgery; 3, manual dilatation is successful in the majority of cases. The trained hand can best estimate the amount of continuous pressure necessary for dilatation; 4, in a few cases in which the cervix is long and unobliterated it will be necessary to use Dührssen's Cæsarean section; 5, as a method of checking hæmorrhage rapidly or in cases in which delay is accompanied with exhaustion if the delivery were accomplished *per vias naturales*, it would be well to consider the conservative Cæsarean section.

By J. G. LEIGH.

2. **Laryngeal Paralysis.**—Barwell states that in a knowledge of the appearance and of the causes of laryngeal paralysis we have an important aid to diagnosis in many obscure cases. Many laryngeal palsies give rise to no symptoms whatever, and cannot be diagnosed or even suspected without the use of the laryngoscope. In the common form—abductor paralysis—there need be no disturbance of vocalization. When abductor paralysis has occurred the affected cord lies in the middle line; during phonation the sound cord adducts to meet it and the larynx appears normal. But on inspiration the affected cord remains stationary, while the sound one is drawn outwards and backwards. The voice is not altered, but there is some dyspnoea on active exertion; in children this may be so severe as to necessitate tracheotomy. In bilateral paralysis the cords are drawn closer together on inspira-

tion, and dyspnoea is a marked symptom. It is inspiratory and is accompanied by stridor. As severe paroxysmal exacerbations may occur at any time and prove fatal, tracheotomy should always be done as a precautionary measure. Phonation is good, but has a breathless character. The lesion causing the paralysis may be situated (1) in the medulla; (2) at the base of the brain; (3) in the vagus; or (4) in the recurrent laryngeal nerve. In the first two classes neighboring nuclei are prone to be affected as well, so that there is usually concomitant paralysis of the soft palate, uvula, and pharynx. Persistent frequency of the pulse is an important sign of bulbar disease. Bulbar paralysis are frequently bilateral, tabes dorsalis being the commonest cause of such paralysis. Syphilitic nuclear disease, gummata at the base of the brain, and syphilitic pachymeningitis are also common causes of abductor paralysis. Disseminated sclerosis seldom produces paralysis. Of peripheral causes neuritis is a frequent factor; it may be toxic (lead, alcohol, or arsenic), or infective (diphtheria, typhoid, influenza, etc.). Paralysis from involvement of the vagus (3) is usually due to compression of the nerve, from, (a) aneurysm; (b) enlarged glands, usually tuberculous; and (c) cancer of the œsophagus. Rarer causes are mediastinal growths, pulmonary tuberculosis, goitre, etc. Aneurysm is the most frequent of all causes of laryngeal palsy, being the most often occurring. In addition there may be glottic spasm, and the peculiar "brassy" cough, which later becomes wheezing in character. Left vocal cord paralysis may be the earliest sign of aneurysm. Tuberculosis causes paralysis either by pressure of bronchial or tracheal glands, or by involvement of the nerve in a tuberculous infiltration at the apex of the lung. The association of laryngeal palsy with a thyroid tumor, though suspicious, is no conclusive proof of malignancy. Adductor palsies always affect the phonatory function. They are usually bilateral and are not due to organic disease of the nerve path, but either to a neurosis (functional aphonia) or to local disease, such as laryngitis. Functional aphonia is a common manifestation of hysteria, but anything which makes the effort of phonation more difficult than usual (such as debility, thickening of the cords, or laryngeal catarrh), predisposes to this affection. It occurs in men as well as women; the onset is sudden, and so is the recovery. Paralysis is very seldom complete, and unilateral adductor paralysis is extremely rare. It is due to local interference with the muscles and in a few instances to toxic causes.

3. **Leishman Bodies.**—Rogers has previously described the development of flagellated organisms from Leishman bodies—the organisms found in cases of cachexial splenic fever. His experiments show that the best medium for the development of these flagellated organisms is acidified citrated blood. Now such an acid medium is supplied in the stomachs of many blood sucking insects, so that the most likely mode of infection is through the means of some such bit-

ing insect. While the parasite is never found in the peripheral circulation, yet it is frequently present in papules in the skin, especially on the thighs and other parts open to the attacks of fleas and bedbugs, but not to mosquitoes. So that the communicability of endemic cachexial fever should be recognized, and any infected and uninfected persons prevented from sleeping in the same bed or in beds placed side by side. This precaution is especially desirable in the case of children who are very prone to the disease and in whom it is very fatal.

5. **Jejunostomy.**—Robson in describing a new method of jejunostomy, states that the indications for the operation are extensive cancer of the stomach too advanced for gastrectomy, and general simple cicatricial contraction of the stomach, due to the swallowing of caustic fluids. The bowel must be so placed as to permit the passage onward of the bile and pancreatic fluid poured into the intestine above the artificial fistula, and to allow of food being introduced through the fistula without fear of regurgitation. The author's operation consists in taking a loop of the beginning of the jejunum just sufficiently long to reach the surface without tension; the two arms of the loop are short circuited, about three or four inches from the surface. The short circuiting being done either by means of sutures around a decalcified bone bobbin, or by sutures alone. A small incision is then made into the top of the loop just large enough to admit a number twelve Jaques catheter, which is inserted and passed for three inches down the distal arm of the loop; this is fixed to the margin of the incision in the gut by means of sutures. The top of the loop is fixed to the skin by one or two stitches, and the wound is closed. The patient can then be fed at once with peptonized milk and brandy. If necessary the short circuiting may be omitted. The operation of jejunostomy, which has a mortality of ten to twenty per cent., would be very seldom called for if the early diagnosis of gastric cancer was insisted on. In patients at or after middle age, the occurrence of gastric pain and vomiting, with loss of weight and energy, and anemia, the possibility of cancer should be recognized. If no improvement takes place in two or three weeks, an exploratory operation is more than justified.

6. **Second Dentition.**—Armstrong calls attention to the importance of a sound second dentition to the general health, and, *vice versa*, the necessity of good health in the insurance of a sound dentition. The influence of rickets as a retarder of dentition is well known, and also that of cretinism. Hereditary syphilis is said to accelerate the advent of the teeth; this while true as regards the first is very doubtful as regards the second dentition. Acute disease, such as the exanthematous fevers, may leave permanent results in the enamel with a disastrous sequel in the history of the teeth. Such "honeycombed" teeth invariably become the subjects of early decay. Retronasal adenoids interfere with dentition by altering the shape of the arch of the pal-

ate, and causing crowding of the teeth. The same is true of thumb and lip sucking, which forces out the upper alveolus. The diseases actually due to the second dentition are few in number—among them may be mentioned stomatitis and oral sepsis. The influence of dentition upon concurrent general disease is manifested chiefly in the neuroses—*e. g.*, in epilepsy, where at times dentition initiates the onset, and at others increases the frequency of the fits.

7. **Typhoid in the Fœtus.**—Hicks and French report a case of typhoid fever occurring in a pregnant woman aged twenty-four years. She was seven and a half months pregnant, and on the eighth day of the disease was delivered of a live fœtus, which died an hour later. The mother died on the twenty-fourth day of the disease. The mother's blood at the time of labor gave a positive Widal reaction, but the fœtal serum reaction was negative. The authors have studied the literature of the subject with the following result: In half the cases of typhoid during pregnancy, the bacilli have passed into the fœtal blood. In such cases they were probably circulating freely in the mother's blood. The duration of the typhoid fever seems to be an important factor in determining infection of the fœtus, and the question is raised whether in such cases early labor should not be induced as early as possible in order to prevent infection of the child. That the typhoid agglutinin does occur in the serum of a fœtus born of a mother suffering from typhoid fever, seems to be well established, but the evidence is slender that the typhoid serum reaction can occur in the fœtus in which no bacilli have been found. If so, either the fœtus receives its agglutinins directly from the mother, or its own tissues react to the maternal poisons. Typhoid fever occurring during pregnancy does not affect the prognosis or alter the course of the disease, but its effect on the pregnancy is bad. In most cases abortion or premature labor takes place.

8. **Yeast in Tuberculosis.**—Huggard and Morland record the results of their observations on the effect of yeast taken internally in tuberculosis. The yeast is supposed to act by means of its nuclein causing a leucocytosis, and further because nuclein is bactericidal. In almost every case some improvement was noted. In five cases tubercle bacilli disappeared from the sputum and the disease was seemingly arrested. In seven cases marked improvement took place. In eleven cases of medium severity and doubtful prognosis, all but one showed improvement. Twelve advanced cases of bad prognosis appeared to be benefited, at least for a time. A steady rise in the opsonic index was noted in 21 out of 25 cases in which it was examined for. This index shows the degree to which the serum of a person's blood prepares tubercle bacilli for being taken up and digested by normal white blood corpuscles. The yeast employed was of several different kinds, the dose being two or three grammes taken once a day in cold or tepid milk or water. Some patients noticed no influence;

others felt a sense of well being, while a few had a feeling of exhilaration. It did not appear to have any influence on the temperature of febrile patients.

9. Scarlet Fever.—Gordon divides cases of scarlet fever into three types: 1. The simple variety, where the attack presents no special distinguishing features and is not at any time severe. Little treatment is needed, except the preservation of a sepsis. 2. In scarlatina anginosa the patient may have an intense faucial inflammation which is progressive. There is deep ulceration and sloughing, with absorption and the production of a general septicæmia. Otorrhœa almost certainly follows, and late nephritis is not uncommon. 3. In the toxæmic type, the patient receives a large dose of the scarlatinal poison at the onset. Death may occur in twenty-four hours before the rash appears. The patient is comatose, cyanosed, and evidently intoxicated. In the treatment of these cases the author has been using a polyvalent antistreptococcic serum, derived from injections of various strains of streptococci. It is very improbable that the phenomena of scarlet fever are due to a pure infection with any organism. Streptococci in mixed culture are always found. In fifty-five cases of toxic scarlatina in which it was used, death took place in thirteen—a mortality of 23 per cent. The general scarlatinal mortality of the hospital was reduced from 6.1 to 3.1 per cent. Large doses of 50 to 100 cubic centimetres were used, and no ill effects were observed other than a transient erythema.

GLASGOW MEDICAL JOURNAL

May, 1905.

1. Acute Fatal Pneumococcic Pleurisy, Resembling Clinically Acute Lobar Pneumonia, with Remarks Upon the Relationship of Pneumonia to the Pneumococcus, By STEVEN.
2. Case of Cerebrospinal Meningitis Following Scarlet Fever, By McKENZIE.
3. Thickening of the Ribs in Chronic Empyema, By EDINGTON.
4. Case of Traumatic Stretching of the Lower Cervical Nerve Roots, with Remarks on Some Allied Conditions, Including the Mechanism of Their Production, By MORT.

1. Acute Fatal Pneumococcic Pleurisy.—Steven reached the following conclusions: 1, An acute, rapidly fatal pleurisy with effusion, originating spontaneously or idiopathically, may run a clinical course not to be distinguished from that of a severe acute lobar pneumonia; 2, the virulence of Fränkel's pneumococcus may occasionally expend itself upon the pleura rather than upon the parenchyma of the lung itself.

2. Cerebrospinal Meningitis Following Scarlet Fever.—McKenzie states that meningitis is a rare complication of scarlet fever. Henoch is quoted as saying that the marked cerebral symptoms which are found in severe cases of scarlet fever apparently do not depend upon meningitis. The usual pathological findings are hyperæmia

or œdema of the pia mater and of the brain substance similar to that which occurs under other conditions. The symptoms are usually due to vascular engorgement, resulting from the lowering of the heart's energy, which may also lead to thrombosis of the sinuses, but they are never due to regular inflammatory products. Meningitis may occur as the result of scarlet fever, but its clinical symptoms would be hard to differentiate from those of malignity. In the author's case in addition to well marked meningeal symptoms, there was an intense restlessness resembling that which is characteristic of anginose and malignant scarlet fever. The infective agent doubtless was the streptococcus pyogenes and the source of infection was probably the throat. The infection may have been carried to the cerebrospinal membranes by the lymphatics of the neck or by the blood. The meningitis in this case complicated a second attack of scarlet fever.

4. Case of Traumatic Stretching of the Lower Cervical Nerve Roots.—Mort's summing up of his statements are as follows: 1, The trauma, according to the statement of the patient, was not due to a previously existing neuritis, or to the usual causes of brachial neuritis, alcohol, syphilis, or intrathoracic neoplasm. There were no motor symptoms; 2, the symptoms were limited to the upper limbs, and the cause was probably to be found in the posterior nerve roots at their origin; 3, the precise location was the fifth or sixth nerve root, and this was stretched by the sudden forcible flexion of the spinal column at the moment of injury.

Proceedings of Societies.

AMERICAN GYNÆCOLOGICAL SOCIETY.

Thirtieth Annual Meeting, Held at Niagara Falls, N. Y., May 25, 26, and 27, 1905.

The President, Dr. E. C. DUDLEY, of Chicago, in the chair.

The Address of Welcome was made by Dr. WOLF, of Niagara Falls, and the response by Dr. ELY VAN DE WARKER, of Syracuse.

Accidental Rupture of the Non-Parturient Uterus.—Dr. G. W. JARMAN, of New York, said in this paper that he wished to include in his category those uteri also which had been perforated. The condition was not a rare one, and it was perfectly obvious that many cases were never reported. It resulted most frequently after dilatation, curettage, and the use of the uterine sound. In connection with cancer and other diseases which affected the integrity of the tissues of the organ, perforation and rupture frequently occurred. He narrated five cases of women having reached the fourth month of pregnancy. Abdominal section was done in each case, and one case was fatal from sepsis. Abdominal section with drainage through the vagina was usually indicated, the abdomen being irrigated with sterile water. These and similar cases admonished us as to the need of greater care in the

use of the dilator, the curette, and the sound. If the patients were operated upon early and the lesion was not too extensive, there was very little mortality, either from the accident or from the operation for its relief.

Dr. A. P. DUDLEY, of New York, reported that he had had experience with accidents of this character.

Dr. H. J. BOLDT, of New York, thought the abdomen should be opened after this accident if infection had resulted; otherwise it was better to do nothing. Curettage was frequently accompanied by perforation, but with few or no resulting symptoms.

Dr. F. HENROTIN, of Chicago, had seen five cases of this accident, but did not consider that it was attended with serious results as a rule.

Dr. A. F. CURRIER, of Mt. Vernon, N. Y., had seen a number of cases in his own practice and that of others. He could not recall a case which had resulted fatally. One must be prepared to consider the operation of hysterectomy as an alternative measure in certain of the severer cases with sepsis and those in which the uterine tissues were in a more or less disintegrated condition. Removal of the focus of infection and drainage through the vagina would save some lives which would otherwise be lost.

Dr. A. LAPHORN SMITH, of Montreal, did not believe that rupture or perforation could occur as a rule except as a result of violence or carelessness.

Dr. CLEMENT CLEVELAND, of New York, believed that one should distinguish between the dull and the sharp curette in considering the question. He had observed the accident with the sharp, but not with the dull curette. He especially objected to the sharp curette being so frequently used by the general practitioner, and believed that this and other gynecological operations which belonged to the expert should not be performed by others. The dull curette was by far the safer instrument except in the hands of experts. The sharp curette should not be used by the general practitioner.

Dr. W. H. MOSELY, of Baltimore, called attention to the fact that rupture or perforation occurred below the os internum in many of the accidents of this character. He approved of the use of the dull curette for purposes of diagnosis, but the sharp one was better if tissue was to be removed. There was frequently more danger in the use of the dull than in that of the sharp curette.

Dr. W. H. WATHEN, of Louisville, thought there was no field for the use of the dull curette by the expert for the removal of loose tissues. A skilled operator should never perforate the uterus. He urged that the still dilators should seldom be used for any purpose, their field of absolute usefulness being very limited.

Dr. ELY VAN DE WARKER, of Syracuse, attributed the risk of rupture of the uterus to two elements: one, the operator, being a variable quantity, and the other, the instrument, being permanent and dangerous. He agreed that dilators were used too frequently. Injury might come

from the work of the expert as well as the inexperienced and inexperienced, but the former would know how to meet the emergency, while the latter would not.

Dr. S. C. GORDON, of Portland, Me., concurred in the view that the uterus should be removed if the injury was a serious one, and that nothing should be done if the lesion was not extensive.

Dr. P. A. HARRIS, of Paterson, N. J., reminded the society that many cases of so called dilatation were divisions, tearing, and rupture, following unskillful treatment or unfavorable conditions in the tissues of the patient.

Dr. T. A. REAMY, of Cincinnati, believed that he had perforated the uterus even when exercising extreme care. He had seen no serious results in a number of cases which had fallen to his experience.

Dr. JARMAN expressed the belief that after almost any accident of this nature, whether severe or mild, an incision should be made in the vaginal vault, and gauze or a tube introduced for drainage. It must not be forgotten that the uterus could be perforated as well with the dull as with the sharp curette. He agreed that the uterus should be removed if the conditions were severe enough to warrant it.

Retroversio Uteri; a New Operation for Its Radical Cure.—Dr. A. W. JOHNSTONE, of Cincinnati, read a paper in which he said that he regarded the first step in either retroversion or prolapse as due to a stretching of the uterosacral ligaments. The round ligaments did not support the uterus; they merely fulfilled the functions of guy ropes to steady it. These views were confirmed by the study of the anatomy of the uterus in the higher mammalia, in which it was quite evident that the uterosacral ligaments held the cervix in position, the cervix and body joining at an obtuse angle. The anatomy of the uterus and its surroundings showed the faultiness of the operations on the round ligaments, likewise of the operations which attached the uterus to the abdominal wall, and also those in which the uterine body was attached to the vagina. Loss of tone in the uterosacral ligaments, due to a low grade of infection extending to them from the uterus or other contiguous structures, or in some cases to violence, was followed by their stretching, and then prolapse and retroversion resulted. This explanation of the mechanics of the subject justified the use of the pessary and showed why and how pessaries were often useful. The operation which was suggested consisted in making a two inch longitudinal incision through the vaginal vault, parallel with the long axis of the vaginal portion of the cervix, introducing the finger and bringing forward each uterosacral ligament in succession, and taking a loop in each with silk sutures. A transverse incision should not be made, as it would probably result in cutting through the ligaments at their attachment. This operation held the uterus permanently in its normal position unless the tissues should again become shortened and again should stretch.

(To be continued.)

Official News.

United States Public Health and Marine Hospital Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the period from June 10 to June 10, 1905:

Smallpox—United States.

Places.	Date.	Cases.	Deaths.
Dist. of Columbia—Washington	June 3-10	2	1
Florida—Jacksonville	June 3-10	1	2
Illinois—Danville	June 1-8	5	1
Indiana—South Bend	June 3-10	16	2
Louisiana—New Orleans	June 3-10	16	1
Massachusetts—Lowell	June 3-10	1	1
Michigan—Detroit	June 8-10	2	2
Michigan—Grand Rapids	June 3-10	4	1
Missouri—St. Joseph	June 3-10	5	1
Missouri—St. Louis	June 3-10	3	1
Nebraska—Omaha	June 3-10	1	1
New York—New York	June 3-10	1	1
Pennsylvania—Lebanon	June 3-10	1	1
Pennsylvania—York	June 3-10	3	3

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending June 14, 1905:

ALTREE, G. H., Acting Assistant Surgeon. Granted leave of absence for thirty days from June 10th.

BAILEY, C. W., Acting Assistant Surgeon. Department letter of May 10th, granting Acting Assistant Surgeon Bailey leave of absence for twenty-six days, amended to read ten days from June 5th.

BIERMAN, C. H., Pharmacist. Department letter of May 19, 1905, granting Pharmacist Bierman leave of absence for thirteen days from June 7, 1905, revoked.

BLAIN, A. C., Acting Assistant Surgeon. Granted leave of absence of fourteen days from June 14th.

BLUE, RUPERT, Passed Assistant Surgeon. Granted leave of absence for sixteen days from June 22, 1905.

CARLTON, C. G., Pharmacist. Granted leave of absence for one day from June 9, 1905, under paragraph 210 of the regulations.

CUMMING, H. S., Passed Assistant Surgeon. Detailed for duty on special Revenue Cutter Service board. June 8, 1905. Detailed to represent the Service at meeting of American Medical Association at Portland, Ore., July 11th to 14th.

DREW, A. D., Acting Assistant Surgeon. Granted leave of absence for five days under paragraph 210 of the regulations.

FOSTER, M. H., Passed Assistant Surgeon. Granted leave of absence for one month from June 11th.

FRANCIS, EDWARD, Assistant Surgeon. Granted leave of absence for seven days.

HUNTER, W. R., Acting Assistant Surgeon. Granted leave of absence for ten days from June 11th.

ROSENAU, M. J., Passed Assistant Surgeon. Detailed to represent the Service at meeting of American Medical Association at Portland, Ore., July 11th to 14th.

SIMONSON, G. T., Acting Assistant Surgeon. Granted leave of absence for two days from June 11th.

SPRAGUE, E. K., Passed Assistant Surgeon. Granted leave of absence for one month from June 27th.

SIMPSON, W. G., Passed Assistant Surgeon. Granted leave of absence for five days from July 5th.

WALKLEY, W. S., Acting Assistant Surgeon. Granted leave of absence for two days from June 16th.

WIGHTMAN, W. M., Acting Assistant Surgeon. Granted leave of absence for two days under paragraph 210 of the regulations.

WILSON, R. L., Passed Assistant Surgeon. Granted extension of leave of absence for seven days.

Board Convened.

Board convened to meet at the marine hospital, New Orleans, June 13, 1905, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board—Surgeon A. C. SMITH, chairman. Assistant Surgeon F. H. McKEON, recorder.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending June 17, 1905:

ALLEN, JOHN H., First Lieutenant and Assistant Surgeon. Granted ten days' leave of absence.

BLANCHARD, R. M., First Lieutenant and Assistant Surgeon. Leave of absence extended twenty days.

EWING, CHARLES B., Major and Surgeon. Left Columbus Barracks, Ohio, with recruits, en route to Vancouver Barracks, Washington.

GIBSON, ROBERT J., Major and Surgeon. Having reported at San Francisco, Cal., will proceed to and take station at Fort Logan, Colo.

GILCHRIST, HARRY L., First Lieutenant and Assistant Surgeon. Ordered to report in person on July 17, 1905, to Major William H. Arthur, Surgeon, president of the examining board, Army Medical Museum Building, Washington, D. C., for examination to determine his fitness for advancement to the rank of captain.

GORGAS, WILLIAM C., Colonel and Assistant Surgeon General. Appointed a member of a board of officers to meet at Ancon, Canal Zone, Isthmus of Panama, July 17, 1905, for the examination of medical officers to determine their fitness for promotion or advancement.

KENNEDY, JAMES M., Captain and Assistant Surgeon. Ordered to accompany troops from Benicia Barracks, Cal., to Vancouver Barracks, Wash., returning to station at United States General Hospital, Presidio of San Francisco.

KREBS, LLOYD LE R., First Lieutenant and Assistant Surgeon. Ordered to proceed from San Francisco, Cal., to Vancouver Barracks, Wash., as witness before a G. C. M.

LYSTER, THEO. C., First Lieutenant and Assistant Surgeon. Ordered to report in person to Colonel William C. Gorgas, president of examining board, Ancon, Canal Zone, Isthmus of Panama, for examination to determine his fitness for advancement to rank of captain.

MCCULLOCH, C. C., Jr., Major and Surgeon. Assignment to the Presidio of Monterey, Cal., revoked, and ordered to Fort Meade, S. D.

OWEN, WILLIAM O., Major and Surgeon. Relieved from duty at Fort Logan, Colo., and upon expiration of present sick leave will proceed to and take station at Presidio of Monterey.

PORTER, R. S., First Lieutenant and Assistant Surgeon. Leave of absence extended ten days.

REILLY, JOHN J., First Lieutenant and Assistant Surgeon. Relieved from further duty at Jackson Barracks, La.

REYNOLDS, CHARLES R., First Lieutenant and Assistant Surgeon. Left Army General Hospital, Washington Barracks, D. C., on ten days' leave of absence.

ROBBINS, CHANDLER P., First Lieutenant and Assistant Surgeon. Ordered to report in person on July 17, 1905, to Major William H. Arthur, Surgeon, president of the examining board, Army Medical Museum Building, Washington, D. C., for examination to determine his fitness for advancement to the rank of captain.

SHIMER, IRA, Captain and Assistant Surgeon. Appointed a member of a board of officers to meet at Ancon, Canal Zone, Isthmus of Panama, July 17, 1905, for the examination of medical officers to determine their fitness for promotion or advancement.

STRAUB, PAUL F., Captain and Assistant Surgeon. Appointed a member of a board of officers to meet at Ancon, Canal Zone, Isthmus of Panama, July 17, 1905, for the examination of medical officers to determine their fitness for promotion or advancement.

VAN POOLE, G. McD., First Lieutenant and Assistant Surgeon. Granted thirty days' leave of absence.

WEBBER, HENRY A., Major and Surgeon. Reported for temporary duty at Fort Stevens, Oregon.

The following named medical officers are ordered to report in person on July 17, 1905, to GEORGE H. TORNEY, Lieutenant Colonel and Deputy Surgeon General, at Army General Hospital, Presidio of San Francisco, Cal., for examination to determine their fitness for advancement to the rank of captain:

BISPHAM, WILLIAM N., First Lieutenant and Assistant Surgeon.

GEDDINGS, EDWARD F., First Lieutenant and Assistant Surgeon.

LYSTER, WILLIAM J. L., First Lieutenant and Assistant Surgeon.

PERSONS, ELBERT E., First Lieutenant and Assistant Surgeon.

RUTHERFORD, HENRY H., First Lieutenant and Assistant Surgeon.

WADHAMS, S. H., First Lieutenant and Assistant Surgeon.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending June 17, 1905:

BOGAN, F. M., Passed Assistant Surgeon. Ordered to the Naval Hospital, Yokohama, Japan, for duty.

GUTHRIE, J. A., Surgeon. Discharged from treatment at the Naval Hospital, New York, N. Y., and granted sick leave for three months.

OHNESORG, K., Passed Assistant Surgeon. Detached from the Naval Museum of Hygiene and Medical School, Washington, D. C., June 20th, and ordered home to await orders.

OLSEN, G. M., Assistant Surgeon. Ordered to the Naval Hospital, Philadelphia, Pa.

PRYOR, J. C., Surgeon. Detached from the Museum of Hygiene and Medical School, Washington, D. C., and ordered to duty as a member of the naval and medical examining boards, Washington, D. C.

RODMAN, S. S., Passed Assistant Surgeon. Detached from the *Ranger* and ordered to the *Rainbow*.

SHOOK, F. M., Assistant Surgeon. Ordered to the Naval Hospital, Norfolk, Va.

SUTTON, R. L., Assistant Surgeon. Discharged from treatment at the Naval Hospital, New York, N. Y., and ordered to Washington, D. C., June 22nd, for exam-

ination for retirement and then home to await orders. WILCES, G. L., Assistant Surgeon. Detached from the *Solace* and ordered to the Naval Station, Cavite, P. I.

Births, Marriages, and Deaths.

Born.

TAYLOR.—In Holyoke, Massachusetts, on Sunday, June 4th, to Dr. J. S. Taylor, United States Navy, and Mrs. Taylor, a daughter.

Married.

ACKER—CRANE.—In Detroit, Michigan, on Wednesday, June 7th, Dr. William Fred Acker and Miss Mildred Hoag Crane.

BRENNAN—MCCAHILL.—In Larchmont, N. Y., on Wednesday, June 7th, Dr. James H. Brennan and Miss Julia McCahill.

CARR—SCHEMANN.—In Wyoming, Ohio, on Monday, June 5th, Dr. Alvin H. Carr and Miss Anna H. Schemann.

DOWNES—SWEENEY.—In Philadelphia, on Wednesday, June 7th, Dr. Andrew J. Downes and Miss Nora Sweeney.

FUCHSIUS—ENGELHARDT.—In St. Johnsville, N. Y., on Thursday, June 5th, Dr. John Hancock Fuchsuis and Miss Martha Louise Engelhardt.

GORDON—ISENMAN.—In St. Louis, Missouri, on Thursday, June 8th, Dr. F. M. Gordon and Miss Louise Isenman.

HILL—MINOKA.—In Philadelphia, on Tuesday, June 6th, Mr. Charles A. Hill and Dr. Lillie Rosa Minoka.

KNOX—DICKSON.—In Kingston, Ontario, Canada, on Thursday, June 1st, Dr. William J. Knox and Miss Janet Isabella Dickson.

KORFF—VAN REYEN.—In Washington, D. C., on Monday, June 5th, Baron Serge Alexander Korff, of Russia, and Miss Alletta Van Reypen, daughter of Dr. William K. Van Reypen, United States Navy, retired.

TINDALL—HALL.—In Philadelphia, on Wednesday, June 7th, Dr. Morris H. Tindall and Miss Elizabeth M. Hall.

ULRICH—RALSTON.—In Philadelphia, on Wednesday, June 7th, Dr. George A. Ulrich and Miss Hester D. Ralston.

VOSSLER—JONES.—In Brooklyn, N. Y., on Monday, June 12th, Dr. Theodore L. Vossler and Miss Kathryn Lyle Jones.

Died

AUGSBERGER.—In Brooklyn, N. Y., on Thursday, June 15th, Dr. Max Augsberger, in the forty-fifth year of his age.

CHAMBERS.—In Port Jefferson, N. Y., on Monday, June 12th, Dr. Martin Luther Chambers.

CRENSHAW.—In Mt. Washington, Kentucky, on Wednesday, June 7th, Dr. H. F. Crenshaw.

FOWLER.—In Newburgh, N. Y., on Friday, June 9th, Dr. J. Walker Fowler, in the eighty-sixth year of his age.

GARDNER.—In New York, on Monday, June 12th, Dr. Arthur H. Gardner, in the thirty-eighth year of his age.

HARDY.—In Chipley, Georgia, on Thursday, June 8th, Dr. John C. Hardy.

KNIGHT.—In Santa Cruz, California, on Friday, June 2nd, Dr. Benjamin K. Knight, in the sixty-ninth year of his age.

STEWART.—In Philadelphia, on Tuesday, June 13th, Dr. David Dennison Stewart, in the forty-seventh year of his age.

SUTTON.—In Hyattsville, Maryland, on Sunday, June 11th, Dr. Louis James Sutton, in the seventy-fourth year of his age.

TOMPKINS.—In New York, on Monday, June 5th, Dr. Abraham Westervelt Tompkins.

WILLIAMS.—In Charlottesville, Virginia, on Sunday, June 11th, Dr. J. W. Williams, in the sixty-sixth year of his age.

Miscellany.

The Care of the Eyes.—Whatever promotes general hygiene is beneficial to the eyes, says the *Denver Medical Times*, for June, 1905. One should avoid reading while lying down or when exhausted, and sudden changes from the dark to brilliant light. Unspaced type is injurious. Reading on the cars is bad for the eyes, by reason of the oscillating movements requiring the paper to be held too near, causing overwork of the muscles of accommodation. One should carry the head erect and avoid tight neckwear, which causes passive congestion of the head and eyes. Fox advises bathing the eyes twice daily with cold water up to 40 years; and after 50 with water as hot as possible, followed by the cold. The first symptoms of failing sight are hypersecretion of tears, burning of eyelids, loss of eyelashes, and congestion of the mucosa.

Special care of the vision should be exercised by bookkeepers, typewriters, printers, proofreaders, etchers, and engravers. All those engaged in near work should take short intervals of eye-rest. Fox suggests a thin piece of tin sheeting, colored green, blue, or black, or a neutral tinted blotting pad, to be placed under the glazed page while adding up accounts. A shade over the eyes to protect them from the direct rays of light, is very useful. Neutral (arundel) tinted glasses may be used by persons working under high pressure. If possible, the light should come over the left shoulder, and cross lights are to be avoided. The pure white light of the Welsbach burner and electric bulb lacks diffusive power, and is not good for constant work. A pink or arundel shade should be used around the base. Reflectors cause eye strain. Incandescent burners are generally not removed often enough. Blank walls strain the eyes; green discs on the wall and pastoral scenery give relief.

In the first six months of life we should guard the eyesight most carefully from the direct rays of the sun and from clouds of dust. During infancy and early childhood the predominating refractive anomalies are hypermetropia and astigmatism, alone or combined. In the early school years many of these cases pass from the hypermetropic into the myopic defect "through the turnstile of astigmatism." To prevent amblyopia ex anopsia in a squinting eye, proper glasses should be fitted as soon as the child begins to read. Ocular defects are a common cause of apparent mental dullness in children. Asthenopia, chorea, and migraine may also depend on errors of refraction.

Myopia is a disease of civilization. Proper adjustment of glasses prevents increase of the defect, as well as headaches and other complications. Full correction for near and far vision should be obtained all the time. Frequent re-examination and, if need be, refitting of the patient should be insisted upon. Myopic persons should work only by daylight, with frequent rest to the eyes. Stringent restriction of near work is indicated in high, progressive myopia. To prevent myopia all books, sewing, etc., should

be held at a distance of at least 25 cm. from the eyes, the position of the body should be comfortable, and oblique positions of the head must be avoided. Plenty of sleep and outdoor exercise are of prophylactic consequence.

Although the staphylococcus pyogenes aureus is the predominating organism in acute catarrhal conjunctivitis, the primary cause is the conjunctival hyperæmia, so common in large cities, arising from dust, smoke, bright lights, strong winds, exposure to cold, and reflex ciliary strain. The sanguineous exudate furnishes a favorable nidus for the rapid propagation of the germs normally present in the conjunctival sac.

Workers in iron, steel, and stone should protect their eyes by the use of large spectacles containing plane glasses, unless special lenses are required for ametropia. Snowblindness can be prevented by wearing smoked or tinted glasses, but the continued use of these increases the sensitiveness of the retina and makes asthenopic conditions worse.

The leucorrhœa of pregnant women is infectious in from 20 to 40 per cent. of cases. To prevent ophthalmia neonatorum, the woman's genitals should be bathed and syringed with antiseptic solutions before and during confinement. Trachoma is a strictly contagious disease, occurring generally in those who have no regard for the ordinary principles of cleanliness.

Obstetrical Practice in the Country.—Dr. George Harwood, in the *Charlotte Medical Journal*, for June, 1905, writes on this subject: It must be understood that this article does not proceed from the pen of one who sits in a town office and gives his views upon obstetrics in general based upon a city experience, where nurses, consultants, and up to date armamentaria are within easy reach, but upon a country experience solely, comprising 15 years' practice and a radius of at least 40 miles in a sparsely settled country of about 1,500 families, and an average of from 40 to 50 cases yearly, a sufficient basis on which to found a few facts and ideas.

The country practitioner who has a fair yearly average of obstetrical cases for ten years is the equal of most and superior to some of his city brethren, from the fact that, though he may not see so many cases in the aggregate during the same time, he is thrown upon his own resources entirely in the great majority of his cases, consultants and nurses being few and far between.

The city man may possibly be more of an adept with the special instruments needed in abnormal cases for the reason that it is a well recognized fact that there is a greater average of such abnormal cases in large cities than in the country, due to mode of life and environments of the patients, and again there are generally men in the cities who make obstetrics a specialty, who are always at hand to be consulted in such cases, and from such the city practitioner may have opportunities to become more expert in the use of instruments and more up to date in the procedures in desperate cases; besides which cities have their maternity hospitals to which such cases are frequently moved and the attending physician may

there accustom himself to all procedures undertaken in abnormal cases; on the other hand, the country physician meets with all kinds of cases, and in the great majority without help.

There is no class of cases with which a physician has to deal which require such versatile knowledge, such self reliance, so much firmness, and at the same time gentleness, so much patience at one time and celerity of action at another, such power of encouragement, so much sympathy, so much tact from the moment one is called to attend such cases until they can be safely left, as parturition cases, be they normal or abnormal.

It is here that the country physician is seen at his best or his worst, it is here that his self reliance and experience are shown and where his knowledge and skill come into play.

In nearly every case there are two conditions at stake; firstly, the watching and helping of his patients to a safe conclusion of the act of parturition in all of its stages; and it must be remembered that this does not begin with the first stage of labor nor end with the third stage, but begins as soon as he is engaged and ends only when his patient has reached that state of health in which she was before becoming pregnant; secondly, his reputation hangs on his conduct of each case.

Surrounded as the country physician frequently is by the neighborhood grannies and one or more neighbors of the patient who at some future time may need his services, watched closely and sometimes suspiciously, the least untoward occurrence, especially if such occurrence is not foreseen by him and prepared for, is told and repeated to and by the little world of women around him with disastrous results; he may have made a reputation in labor cases, but one slip made and all is swept away, but slowly to return, if ever.

It is always possible, even in the country, occasionally to test the urine of pregnant patients. Write down and send to your patient such simple rules as bear on the management of the bowels, exercise, and diet, such as will appeal to any sensible patient; later on supply an abdominal supporter if necessary, or cut out and send a pattern of one to be made at home and describe how it should be put on and when; such matters, small though they seem, tend to the safety of the woman and at the same time enhance your reputation for carefulness.

When called to attend your patient do not delay in responding to the call and go in as cleanly attire as possible under the circumstances; a twenty mile ride over a muddy road in the rain is not conducive to a neat and cleanly appearance on the part of the attending physician, but a slight mention of these conditions will set you straight with the family and patient. Probably nothing is so abhorrent to a woman about to be confined as the appearance of a slovenly dressed and grimy handed doctor.

If there is time see that the bed is properly fixed; every doctor ought to know how to do this, if any do not, let him learn; do not rush to examine the patient, but, if from watching the

woman you are sure that labor is not far advanced, engage the patient in an encouraging conversation, calming any nervousness which your appearance may have produced. Explain to her what it is necessary for you to do in a gentle but firm way, look around and see that things are as you need them, get acquainted with others in the room, then disinfect and quietly but thoroughly examine; meanwhile encouraging the patient to bear with the procedure and give you plenty of time to make a thorough first examination, and bear in mind that this first examination should be very thorough. Not only should the condition of the neck of the womb, and if possible, the position of the fœtus be found, but the bladder and rectum should be palpated and the presence of any discharge, blood or other material, should be recognized, and then according to what you have discovered at this examination you will know how to proceed as regards attending to any condition which presents itself at this time; if necessary, empty bladder and rectum, using an antiseptic douche or tampon.

Having attended to these matters set yourself to watch the progress of the labor; do not leave the woman if you are sure that your services will be needed in a reasonable time and, above all, do not say too much or guess too much from the first examination, for in nine cases out of ten you do not know half of what will probably be asked you by the anxious or inquisitive attendants; encourage your patient, do not examine often, have your chloroform handy, and if nothing abnormal intervenes during the progress of labor have patience, see that the feet are kept warm, teach the woman how to help herself, have the pillows rearranged as they get too low or too high. These little things are a wonderful help to your patient.

Uterine inertia, hæmorrhage, or adherent placenta may at any time appear to complicate the case, and it is for these conditions that watchfulness is needed and a quick recognition and skill and celerity to overcome them are demanded of the attendant.

Many times you will be asked by the patient or others present to give an idea as to when labor will terminate, but never hazard a guess, as, with the foregoing conditions possible in every case you cannot do so and a simple statement to that effect with a little explanation of why you do not know will quiet the anxious questioners better than evasive answers which will call for more queries and finally leave the impression that such answers proceed from an ignorance on the part of the physician, which is unpardonable instead of unavoidable.

The same watchfulness, sympathy, and skill are needed in the after treatment of all classes of cases as during the time of parturition, until the patient has regained the normal condition of health, and in this after treatment do not forget that there are two instead of only one individuals to attend—mother and baby.

In conclusion, let me say that the obstetrician, unlike the poet, is made, not born, and the best plan for the making of one is country practice.
